**Sternal Puncture in Tropical Diseases**—Schretzenmayr and Lancaster state that in chronic cases of malaria with anemia, splenomegaly and sometimes cirrhosis of the liver a bone marrow picture may be found which is similar to that of pernicious anemia. There are, therefore, grounds for the

liver treatment in cases of chronic malarial anemia. If malarial parasites are found in the blood they can always be found in the bone marrow in tertian, quartan and subtertian malaria. They may, however, be discoverable in the marrow when absent from the blood and therefore sternal puncture should always be tried before spleen or liver puncture is attempted. Chronic myelostomatitis can produce an aplastic change of the bone marrow suggestive of toxemia. Sternal marrow examination is of value in arriving at a prognosis. In smallpox the typical changes in the bone marrow consist of a myelotic reaction combined with an increase of the reticulum and plasma cells. The differential diagnostic value of these observations is stressed in atypical cases of smallpox. In kala-azar the Leishman Donovan bodies appear to be always found in the bone marrow. Filariae and spirochetes can also be found in the sternal fluid. Autogenous and heterogenous sternal fluid injections in cases of secondary anemia have been found useful, especially when blood transfusion was impracticable.

**Treatment of Meningococcic Meningitis with Sulfapyridine.**—Hobson and MacQuarrie tried to find a bacteriostatic agent of lower toxicity than sulfanilamide, with equal or even greater bacteriostatic powers in such concentrations as can be easily given orally or parenterally and with a chemical constitution which makes possible the accurate determination of its fate and its distribution in the body fluids. The drug selected was sulfapyridine. Six cases of meningococcic meningitis have been treated with no deaths. In all six cases the infection was subdued without the use of serum. The clinical evidence suggests that a concentration of 3 mg. or less per hundred cubic centimeters of cerebrospinal fluid will be effective. Absorption from the intestinal tract into the blood stream is rapid and within four hours the drug has always been found in fair concentration, while with continued medication the concentration rises in from twelve to twenty-four hours to much higher figures. In the trial administration of the drug over a period of no longer than eight hours the concentration in the blood reached 10 mg. per hundred cubic centimeters of cerebrospinal fluid or more in some cases. A similar concentration was found in three normal persons. There are, however, striking individual variations in the capacity to absorb the drug and a given individual absorbed the drug more rapidly in health than in disease. The state of the gastrointestinal tract therefore introduces an important though incalculable factor into medication. The drug passes rapidly from the blood stream into the cerebrospinal fluid and there is some evidence that the rate of passage is increased by inflammation of the choroid. Toxic symptoms were unimportant, although in all probability an unnecessarily large dosage was used.

**Effect of Acetylsalicylic Acid on the Stomach.**—Douthwaite and Lintott studied gastroscopically the stomach's response to certain drugs. They found that acetylsalicylic acid (in the form of certain proprietary preparations) is a gastric irritant and may thus cause acute indigestion and hemorrhage or, if taken repeatedly, chronic gastritis. If taken after food or with milk it probably has no deleterious effect. Calcium acetylsalicylate is less irritating.

- Studies on Latent Insufficiency of Ascorbic Acid. E. Codville II, Simonnet and J. Mornard—p. 1745
- Present Status of Treatment of Postoperative Pulmonary Embolism. J. Patel—p. 1748

**Latent Insufficiency of Ascorbic Acid.**—Codville and his associates say that besides scurvy, the extreme form of ascorbic acid insufficiency, there are abortive forms, such as hemorrhagic diatheses and certain forms of rheumatism. These latent forms of avitaminosis constitute also an essential element in some infectious diseases. In their studies on latent ascorbic acid insufficiency they stress first the necessity of utilizing for the determination of the urinary elimination of ascorbic acid, a procedure which permits complete conservation of this acid in the urine. They solved this problem by using hydrochloric acid instead of trichloroacetic acid. Their studies were made on persons between the ages of 20 and 23 years. They emphasize that the daily administration of 100 mg. of ascorbic acid even if continued for more than a month, is not accompanied by a noticeable urinary elimination. The arrest of ingestion leads immediately to the arrest of elimination even in 'saturated' subjects. These observations indicate a real need of the organism and it may be concluded that daily doses of 30 mg. of ascorbic acid, which are recommended by some authors, are far below the real requirements. Moreover it was found that even the administration of large doses (500 mg.) do not result in signs of intolerance. The organism seems to require about 100 mg. of vitamin C daily, but many persons do not receive this quantity in their daily diet. In this connection the authors discuss the ascorbic acid content of certain foods particularly fruits. They show that a lemon contains only about 18 mg. of ascorbic acid and that, if the 100 mg. of vitamin C is to be supplied by the consumption of oranges, four would have to be eaten each day. In view of the importance of ascorbic acid not only in the prevention of scurvy but also in the defense against infectious diseases, the insufficient quantities of vitamin C in the diets, particularly of large groups (boarding schools, military organizations and so on) should be supplemented by the administration of ascorbic acid.

- Thrombo Angitis Obliterans and Mesenteric Infarcts. M. Constantinesco—p. 713

**Implantation of Bone in Tetany and Spasmophilia.**—Following remarks about the pathogenesis of tetany and spasmophilia, particularly about the insufficiency of the parathyroids, Wokressenski gives his attention to the treatment, pointing out that parathyroid extract prepared according to the method of Collip was not produced in Russia until 1937 and that he is as yet unable to judge its efficacy. The therapeutic method introduced by W. A. Oppel in 1926 consists in the subcutaneous implantation of a piece of bone and results in an increase in the calcium content of the blood. After discussing the technique of this implantation the author points out that Leriche, without knowing of Oppel's ideas, has suggested an analogous treatment. Further the author reviews the 113 cases of tetany and spasmophilia that were treated by means of Oppel's bone grafts at the second surgical clinic of the Kirov institute in Leningrad. He divides the 113 cases into four groups. To the first group belong eighteen patients in whom the spasmophilia and tetany constituted the primary disorder and who had the typical symptoms of the disease. This was the only group in which Oppel's bone implantation was really indicated. In the second group, twenty-seven patients, the spasmophilia and tetany only accompanied some other disorder. In these cases there existed only a relative indication

for the osseous graft. The third group, sixty-two cases, includes those patients in whom the pathognomonic signs of spasmophilia and tetany were not present and in whom the diagnosis was based only on secondary signs which are symptomatic also of other disorders. In this group the indications for the bone implantation were insufficient. In the fourth group, six cases, the osseous transplantation was a prophylactic measure, for it was resorted to in order to prevent possible postoperative tetany after strumectomy. Discussing the results obtained in these different groups, the author cites illustrative case reports. The late results, that is, those observable after from two to eleven years subsequent to the treatment, could be traced in forty-two of the patients. On the basis of the observations made on the material analyzed here the author concludes that hypocalcemia in the presence of tetany and spasmophilia is the chief indication for the subcutaneous implantation of a piece of bone. To be sure the osseous graft is utilisable only within certain limits. Its effects cure in most of the moderately severe cases of spasmophilia and tetany, but in the severe cases it can effect only improvement.

Results in Treatment of Hay Fever H U Hartmann—p 1233

**Progressive Muscular Dystrophy**—Stahl states that occasionally there are cases of muscular dystrophy with absolutely normal creatine and creatinine values in serum and urine. A case of this type was observed by the author. The patient was a man who, at the age of 51, sustained a trauma of the vertebral column and who later developed atrophic and hypertrophic processes in the muscles. In its external aspects the case corresponded to the type to which Griesinger applied the term pseudohypertrophic myopathy, which occurs not only during childhood and in familial groups but also in later life and without demonstrable hereditary tendency. The relation between myopathy and trauma is probably of a different nature in the reported case than in the cases described by Ken Kure and others. The creatine and creatinine metabolism was found to be within normal limits, but it cannot be doubted that this man has a severe, progressive myopathy. This case and a description by Curschmann indicate that anomalies in the creatine metabolism present a frequent but only a facultative symptom of myopathy. Recently it has been pointed out again by Netolitzky and Pichler that disturbances in the creatine metabolism and the clinical behavior of muscular dystrophy do not go parallel. These authors observed clinical improvements after malaria therapy and in case of unchanged creatinuria. On the other hand, they report about the retrogression of creatinuria under the influence of aminoacetic acid without simultaneous increase in muscular strength.

\*Clinical and Roentgen Aspects of Tuberculous Sacrocoxitis V Sechi—p 1355  
Pathogenesis and Roentgen Therapy of Spleen in Metrorrhagia at Age of Puberty S T Armando Biasini—p 1377

**Tuberculous Sacrocoxitis**—Sechi made clinical and x-ray observations on twelve patients, children and adults of both sexes who had tuberculous sacrocoxitis. The condition was on the right side in eight cases and on the left side in four. The author found that the main symptoms are pain of a sciatic type and unilateral antalgic lameness. Pain can be provoked by bimanual pressure at the two iliac crests or else at the two trochanters. Lameness with a forward inclination of the trunk is typical of the condition. There may be hypertrophy of the muscles of the buttocks, edema of the limb, scoliosis and abscess formation at the iliac or gluteal regions. The seat of the lesion or the presence of an abscess cannot

be decided by the results of performing rectal palpation. The x-ray examination of the joint is made when the intestine is empty. Early lesions may be seen in the roentgenograms as light shadows of small erosions or as irregular contours of the articular cleft. The x-ray shadows which show alterations of the sacro-iliac joint are dark and precise in the phases of evolution and involution of the disease. The roentgenograms show irregular contours and notches of the bones at the joint, and the presence of one or various zones of rarefaction of the bone around centers of thickened bone (sequestrums already formed or in the process of formation) or sclerosis of the bones. An x-ray sign of importance is the uneven aspect of the pubic bone which appears in the roentgenogram as though it were at a higher plane on the diseased than on the normal side. In the majority of the cases seen by the author sacrocoxitis was secondary to tuberculosis of the respiratory tract. In two cases the condition originated in propagation of tuberculous lumbar spondylitis. According to the author the x-ray study of tuberculous sacrocoxitis is of diagnostic importance as the iconography of the condition is typical.

**Hematoporphyrin in Depressive Psychosis**—Maloberti administered hematoporphyrin hydrochloride to nine patients suffering from depressive psychosis and to two patients with depressive forms of schizophrenia and paranoid psychosis, respectively. The patients were given, for ten consecutive days, an injection of 1 cc of hematoporphyrin solution which contained 2 mg of the drug. The injections were followed by an interval of three days and then by another series of ten injections on consecutive days in doses of 4 mg each. The patients who derive some benefit from the treatment showed it early in the course of the treatment. When the improvement was obvious but slow the second series of injections was administered in daily doses of 4 mg each for fifteen or twenty days. The treatment proved to be harmless and well tolerated in all cases. The amount of hemoglobin, the crisis of the blood and the general condition of the patients improved in all cases. In the group of nine patients with depressive psychosis the treatment gave satisfactory results to the mental condition in seven and failed in two. It failed also to improve the mental condition of the patients with schizophrenia and paranoid psychosis. According to the author, hematoporphyrin has a depressive action on the vagus. It has, however, a stimulative action on hemoglobin, erythrocytes and leukocytes by which action the sympathetic disturbance is compensated.

\*Puerperal Mastitis from Fissures of Nipple Treatment by Filiform Drainage C Stajano and A Achard—p 517

**Puerperal Mastitis**—According to Stajano and Achard, puerperal mastitis is the result of a syndrome of primary infection of a fissure in the nipple which is immediately followed by painful neuritis, spasm of the muscles of the areola and the nipple and retention of milk in one or more lobes of the breast. Puerperal mastitis develops in two different main phases, namely simple and suppurative mastitis. The treatment of early simple mastitis consists principally in application of wet hot compresses on the breast. In the majority of cases, especially if the treatment is administered early in the development of the infection it suffices to control the infection. If the treatment fails or if the patients are seen late when one or more abscesses are already formed, the authors advise filiform drainage. Local anesthesia is applied to the two lower extreme points of the lobe the acini are transfixed with a curved needle (of Reverdin or Hagedorn type) and a bunch of four strands of silkworm gut is left in the acini as a drain.

Gentle manual expression is done on the lobe and the drain left in place for from four to seven days. As a rule the retained milk (or pus) is spontaneously eliminated through the drain and the condition and function of the breast become normal in about one week. In the presence of infection of acini other than those which were drained the treatment can be applied independently to the newly infected acini. The treatment is indicated also in chronic suppuration of fistulas of the breast in lactation. In these cases the tubes and drains which are commonly used are removed and the filiform drainage is applied. As a rule, even in grave cases, complete cure of the breast is obtained in from seven to twelve days. The authors say that they had obtained satisfactory results in a large number of patients who attended one of several clinics or maternity hospitals of Uruguay. The number of cases is not specified.

### Revista de la Facultad de Medicina, Bogotá

7 4596 (Aug.) 1938 Partial Index

\*Roentgen Study of Amebiasis G. Esquerri Gomez—p. 45

**Roentgen Study of Amebiasis**—Esquerri Gomez carried on a roentgen study of the digestive tract in ten patients suffering from chronic amebiasis with symptoms of the digestive tract and without dysentery and also in twenty-five patients who had either acute or chronic amebiasis with acute or repeated dysentery. The examinations were made after administration of the opaque substance by mouth and in some cases also after administration of an enema of the opaque substance. The author found that frequently there is a retarded elimination of the barium sulfate by the stomach, a rapid passage of the substance through the cecum and colon and retarded elimination of the substance by the colon. The duodenum and ileum are normal. The cecum and colon, especially the transverse segment, show an increased number of segmental divisions of different sizes at some segments, whereas other segments are normal. The number of lobules of the cecum and colon may be diminished or lobules may not be present at all in cases of ptosis and dilatation of the colon with diminished tonicity of the walls of the structure. The caliber of the colon is diminished. Barium sulfate is not evenly distributed in the colon. The lack of repletion appears at the same location if the x-ray examination is repeated. The cecum, the sigmoid flexure and the transverse and descending segments of the colon are the most frequently involved. The normal x-ray aspect of large segments of the intestine, including the duodenum and ileum, in the presence of deformities of the cecum and colon by notches and the general aspect of ulcerous colitis are all characteristic x-ray aspects of amebiasis, both chronic without dysentery and acute or chronic with dysentery. Therefore the author regards the x-ray examination of the digestive tract of diagnostic value in amebiasis, especially in the forms which do not give clinical symptoms of the condition.

### Pneumonia from Gaseous Nitric Oxide Compounds—

Cramer describes the pathologic anatomic changes that develop after inhalation of gaseous nitric oxide compounds. He demonstrates with case reports that the inhalation of such gases leads to inflammatory pulmonary processes, which in severe cases take the form of inflammatory edema and terminate in death. In other cases miliary bronchopneumonia develops which on microscopic examination discloses quantities of fibrin erythrocytes and leukocytes in the alveoli, moreover, there are large

syncytial cells which represent regenerating forms of alveolar epithelium. This miliary bronchopneumonia, which in every stage can be diagnosed by roentgenoscopy, may terminate in death, but in many cases recovery results. Occasionally miliary carnification foci develop from it. The author maintains that lobular pneumonia is possible also after inhalation of the nitric oxide gases. In one case he observed within the hepatized portions the same syncytial regenerative forms of alveolar epithelium as are found in miliary bronchopneumonia. He is of the opinion that the forms of pneumonia that develop after inhalation of nitric oxide gases are essentially a result of the inhalation of nitrogen dioxide. Formation of methemoglobin has been observed only occasionally in the fatal intoxications.

### Beitrage zur Klinik der Tuberkulose, Berlin

92 275 394 (Nov. 22) 1938

- \*Tuberculosis in Twins Investigations on Forty Six Pairs E. Uehlinger and M. Künsch—p. 275  
 Disinfection of Wood and Linoleum Surfaces That Have Been Contaminated with Sputum F. Haider—p. 371  
 Experimental Investigations on Influence of Gaseous Substances from Tubercle Bacilli Cultures on Tuberculous Changes D. Sakaki—p. 391

**Tuberculosis in Twins**—Convinced that investigations on twins, as recommended by Diehl and von Verschuer, are the method of choice in determining the role of heredity in tuberculosis, Uehlinger and Künsch made studies on forty six sets of twins, twelve of whom were uniovular, twenty six binovular and eight paired twins. Tuberculous changes were present in one or both of each set of twins. During 1936-1937 the authors visited nearly all the living twins, a roentgenogram of the thorax was made and the environmental and social conditions were investigated. These observations were complemented by earlier case histories and roentgenograms, so that in many instances it was possible to obtain a survey over a number of years. First the authors describe and discuss their observations on the twins with differing heredity, that is, on the binovular twins and the paired twins (twenty six and eight sets, that is, thirty-four sets). In nineteen of these sets tuberculous changes were present in only one of the sets whereas in the other fifteen sets tuberculous changes were present in both. Summarizing the observations on these thirty-four sets the authors say that in thirty-two the behavior as regards tuberculosis was different, in two sets it was identical. In the twelve sets of uniovular twins, however, the behavior as regards tuberculosis was different in five sets and identical in seven sets. In this connection the authors cite the figures obtained by Diehl and von Verschuer. Although these investigators studied a larger material, the ratios between concordance and discordance as regards tuberculosis in enzygotic and dizygotic twins were approximately the same as in the material investigated by Uehlinger and Künsch. From the great similarity in the tuberculosis histories of the uniovular twins and the great differences in these histories in dizygotic twins, it must be concluded that there is a hereditary specific predisposition for the development of tuberculosis. In enzygotic twins the presence of exposure and of an otherwise identical environment always leads to the infection of both twins whereas in dizygotic twins this is not the case in that in many instances only one of a set develops tuberculosis. The authors admit that the problem of genotypically conditioned differences in the susceptibility to tuberculosis requires further investigations.

 Errors in Diagnosis of Scheuermann's Disease and Hydronephrosis B. Bibus—p. 258  
 Dangers of Electric Resection of Prostate A. Stumpf—p. 267

**Raynaud's Disease**—According to Sunder-Plassmann, the characteristic feature of Raynaud's disease as opposed to most organic blood vessel diseases, such as endarteritis obliterans, diabetic gangrene and senile gangrene, is to be seen principally

in vasomotor disturbances. The disease is characterized by the occurrence of attacks during which the pulse remains unaltered. It never begins with gangrene, and endocrine disturbances are frequently present. Essential to the understanding of Raynaud's disease is the most minute knowledge of innervation of the blood vessels, particularly the arterioles and capillaries. The investigations of Stohr, Boeke, Reiser, Sunder-Plassmann, Seto, Yoshitoshi and Hayasi have clearly established that every cell of the blood vessel apparatus, including the capillaries, is under the control of the nervous system. The transmission of the nervous impulses to the cells of the blood vessel wall is accomplished through the nervous terminal reticulum. This consists of a finest network of vegetative neurofibrils partly located in the plasma of the peripheral cells of Schwann and partly in the plasma of the cells of the blood vessel wall. Because of a particular structure, the nervous terminal reticulum possesses considerable peripheral autonomy. The author feels that it would be impossible to denervate a vessel or even a portion of a vessel by an operative procedure. In contrast to endarteritis obliterans there are found no organic alterations in the blood vessel wall in the early stages of Raynaud's disease, which may remain stationary for a number of years. No pathologic changes were reported in the literature in sympathetic ganglions removed at operation. It would therefore appear that Raynaud's disease is a purely functional disturbance of the blood vessel apparatus. It is, however, possible, in the opinion of the author, that if this material was subjected to a particular histologic treatment the results would be different. As long as they are compelled to make observations on fixed material, the demonstration of the finest alterations in the structure of the vegetative nervous substance is possible only through the application of the Bielschowsky method. The author describes severe pathologic alterations in the sympathetic ganglions removed from patients with Raynaud's disease and studied by the Bielschowsky method. He demonstrated definite pathologic alterations in the rami communicantes of the stellate ganglion expressed in pronounced edema of Schwann's sheaths and in pronounced swelling of the axis cylinders. Pathologic changes were likewise found in the finest blood vessel nerve plexuses. On the basis of the observed clinical cases and of the histologic observations and experimental studies the author conceives Raynaud's disease as an entity characterized by localized toxic damage, result of alteration in the vegetative nervous substance central as well as peripheral. At a certain stage of the disease this alteration becomes morphologically demonstrable with the use of a special histologic technique. As a result of these alterations there arises a certain hyperergic transformation of the nervous system supplying the blood vessels. Localizing factors such as cold or psychic emotions bring about attacks of evident circulatory disturbances particularly in parts of the body readily seen and exposed to chilling influences. This circumstance justifies the further supposition that the hyperergic vegetative nervous substance undergoes structural alteration in Raynaud's disease, which becomes morphologically demonstrable with our rather coarse methods only at a later stage. The author feels, however, that with improved histologic technique the negative observations will become more and more rare. Sympathectomy accomplishes no more than the removal of an intermediary station and brings about an improvement in the disease picture through the dilatation of the blood vessels, which in its turn neutralizes and removes metabolic products within the damaged tissues. The author found it useful to administer after sympathectomy, in order to prevent recurrence, dried thyroid tissue and thiamin chloride.

**Intrathoracic Lipoma**—Fulde collected and analyzed thirty-six cases of intrathoracic lipoma reported in the literature since Cruveilhier in 1856 made the first diagnosis of the condition in the living. To these he added four cases from Sauerbruch's clinic. Three of these were cured by operative intervention. According to their localization the tumors may be divided into two groups, a completely intrathoracic and one in which the growth is both intrathoracic and extrathoracic. The physical characteristics of the growth permit of its surgical removal. The earlier mortality of surgical intervention has been markedly lowered in the last few years.

\*Scarlatiniform Exanthems in Infections with *Staphylococcus Aureus* Haemolyticus A Dohmen—p 1689  
\*Sjogren's Syndrome, an A Hypovitaminosis W Stahel—p 1692

**Scarlatiniform Exanthems in Staphylococcal Infections**—Dohmen calls attention to a report by von Bormann about the discovery of a toxin resembling Dick toxin in bouillon cultures of various bacteria. Von Bormann observed that the filtrates of thirty-eight cultures of *Staphylococcus aureus* haemolyticus produced a cutaneous erythema similar to the Dick reactions. Previous admixture of therapeutic scarlet fever serum, that is, of streptococcus serum, prevented this reaction in seventeen of the staphylococcus filtrates, moreover, antitoxic staphylococcus serum weakened the erythema producing factor of the staphylococcus filtrates as well as of the Dick toxin. However, one erythema producing component of the staphylococcus filtrates could be counteracted by neither of the two serums. Such toxins, which resemble the Dick toxin, could be detected also in a number of other bacteria (pneumococci, *Staphylococcus albus* anhaemolyticus and non-hemolyzing streptococci). It was concluded that all these bacteria are capable of forming a toxin which resembles that of the scarlet fever streptococci. The author reviews reports on staphylococcal infections that produced symptoms similar to or identical with those of scarlet fever. He cites three cases described by F A Stevens and one case reported by Glanzmann and then describes the clinical histories of three cases observed at his clinic. Two patients were men aged 25 and 46 and one was a woman aged 35. All three presented the clinical aspects of typical scarlet fever. Two of the patients had earlier passed through scarlet fever, one during childhood and another one only a year before the present illness. The present attack of scarlatiniform exanthem could be traced in all three patients to a wound infection with *Staphylococcus aureus* haemolyticus. No hemolytic streptococci could be detected and the exanthem could be counteracted only by antitoxic staphylococcus serum but not by streptococcus serum. These two factors indicate an etiologic connection between the staphylococcal infection and the scarlatiniform exanthem. The author concludes that these observations militate not against but for the streptococcal etiology of true scarlet fever.

**Sjogren's Syndrome, an A Hypovitaminosis**—Stahel says that the syndrome described by Sjogren is a little known systemic disease of which will show a greater frequency than heretofore assumed. The syndrome is characterized by great dryness of all mucous membranes, resulting from deficient secretion of the glands, particularly the lacrimal and the salivary glands, those of the upper respiratory tract, the sweat glands and the glandular apparatus of the stomach. As sequels of these deficient secretions there develop lack of tear secretion, keratoconjunctivitis sicca or keratitis filiformis, xerostomia, rhinopharyngotracheobronchitis sicca with impairment of the act of swallowing and of the olfactory and gustatory senses, deficient sweating, achylia gastrica, impairment of the tolerance for carbohydrates, general weakness, lack of appetite, muscular atrophy, fever and anemia. The disorder occurs almost exclusively in women of the postmenopausal age, and a chronic polyarthritis exists in 80 per cent of the cases. After citing several investigators who have published reports about this disorder, the author says that some cases have been erroneously diagnosed as Sjogren's syndrome. Xerostomia and keratomalacia were known before as isolated symptoms and as such cannot be identified with Sjogren's syndrome. If this is done erroneous conclusions might be drawn, such as that the disease is equally frequent in the two sexes. The author gives a detailed description of a case showing a complete range of symptoms, which has been under his observation for some time. A woman aged 64 in whom the disorder developed in two phases, had a slowly progressing polyarthritis deformans from the age of 30 to the time of the menopause. After the

characteristic the other symptoms developed. In the discussion of this case the author cites factors which convinced him that Sjogren's syndrome is a systemic disorder with functional disturbances in the ectodermal and endodermal tissues, the cause of which is a vitamin A deficiency and in the manifestation of which disturbances in the mineral content and in the endocrine apparatus play a part. The vitamin A content of the average diet is insufficient in these cases, but the administration of large doses of vitamin A is effective. The woman whose history is reported was given daily 10,000 biologic units of vitamin A for a period of several months. Under the influence of this treatment the inflammatory manifestations on all mucous membranes subsided, the olfactory and gustatory functions became normal, swallowing became easier, sweating returned, the conjunctivitis and photophobia disappeared and the general condition was greatly improved.

\*Fatalities from Extrapulmonary Tuberculosis. Their Part in Total Fatalities from Tuberculosis. R. Ingelmann—p. 145

Tubercle Bacilli of Reduced Acid Fastness and Virulence. Marie Maxim—p. 155

**Fatalities from Tuberculosis.**—Ingelmann discusses the statistics on the fatalities from tuberculosis in Germany during the years 1914-1934 pointing out that the fatalities from this disease were reduced by nearly one half during the period although there was a considerable increase during the war years 1916 to 1918. He also compares the fatality rates from tuberculosis in the different sections of Germany and then analyzes the statistics from certain sections of the country, giving especial attention to the fatalities from extrapulmonary tuberculosis. He emphasizes that the fatalities from tuberculosis should always be differentiated into those from pulmonary tuberculosis and those from tuberculosis of other organs for whereas the figures for the fatalities from tuberculosis in general and from pulmonary tuberculosis show a declining tendency, those for the fatalities from extrapulmonary tuberculosis, including military tuberculosis do not do this. He does not consider it advisable to separate military tuberculosis from the extrapulmonary tuberculosis and classifies it with the pulmonary form. The group of extrapulmonary tuberculosis is not uniform. It is of essential importance for the statistics whether certain forms are regarded as secondary or as primary forms. Necropsies are of great value in determining to what extent such forms as intestinal tuberculosis, tuberculous meningitis or military tuberculosis may be considered as basic disease or as a secondary cause of death. The exactness and arbitrariness of some diagnoses cause considerable deviations in the percental portion of the tuberculosis of extrapulmonary organs in relation to the fatalities from all forms of tuberculosis. The author analyzes fatalities from the various forms of extrapulmonary tuberculosis, discussing in turn abdominal, peritoneal, cutaneous, pleural, renal, glandular, military, meningeal, intestinal and osseous tuberculosis. He shows that the separation of military tuberculosis and of tuberculous meningitis is important, since both groups indicate infectious tuberculosis. Records of cases of military tuberculosis indicate that military dissemination may take place during all stages of tuberculosis. Tuberculous meningitis takes the first place as regards incidence. Tuberculous pleurisy is extremely rare as a primary cause of death. Renal tuberculosis may develop as an ascending tuberculosis and is not necessarily combined with pulmonary tuberculosis. Glandular tuberculosis is rarely the cause of death. Intestinal tuberculosis is regarded by the author as usually of the secondary type. Osseous tuberculosis is especially noteworthy, because of the comparatively frequent involvement of the vertebral column and of the fact that it occurs chiefly in women (twenty of twenty-nine cases). In the last part of his report the author takes up the frequency with which tuberculosis concurs in several members of one family. He shows that, in the material analyzed by him, 8 per cent of the fatalities from tuberculosis were of this group.

**Cholesterol Content in Multiple Sclerosis.**—According to Fichtler and Reissner, the relations between the lipid metabolism and multiple sclerosis have been investigated repeatedly, ever since Warburg expressed the opinion that a lipolytic ferment is the cause of the destruction of the myelin sheaths. Some investigators searched for the chemical constituents of the myelin sheaths and for the products of decomposition and detected an increase in the cholesterol content of the blood serum and of the cerebrospinal fluid. However, since an excessive cholesterol content is absent in diseases that are accompanied by great destruction of nervous substance, it is improbable that the elevation of the cholesterol content is simply the result of the destruction of the myelin sheaths. The authors, who for different reasons made studies on the serum cholesterol content of patients with multiple sclerosis, found that the cholesterol values are not constant but undergo fluctuations. Since many aspects of the cholesterol metabolism are still obscure, they studied the cholesterol content of the serum in a large number of cases of multiple sclerosis. In tables they indicate the cholesterol values (total, esterized and free cholesterol) in the different forms of multiple sclerosis: (1) in new cases or in new exacerbations, (2) in stationary and slowly progressive cases and (3) in controls who had various neural disorders. They also show diagrams indicating the cholesterol fluctuations in the various types of cases and finally show tabular reports of the changes taking place under the influence of various types of treatment. Summarizing their results, they state that a noticeable increase in the serum cholesterol content is detected only in the new cases of multiple sclerosis. In the course of clinical improvements this hypercholesteremia decreases to normal values. If in the course of stationary and slowly progressive cases improvement in the condition of the patient is brought about by means of treatment this improvement is usually found to be accompanied by a temporary increase in the cholesterol content. This hypercholesteremia which is observed in the course of new exacerbations or of clinical improvements of chronic cases of multiple sclerosis is regarded as an accompanying symptom or as a part of the defense measures of the organism.

\*Agglutination of Sheep Blood Corpuscles in Patients' Serums in Illumination of Serodiagnosis of Infectious Mononucleosis. M. Kristensen and H. Meyer—p. 1081

**Sheep Corpuscle Agglutination in Infectious Mononucleosis.**—Kristensen and Meyer examined the serums of 862 persons, including sixty-four tuberculous persons treated with vaccine against colds. In 449 (52 per cent) there was no agglutination, 387 (45 per cent) gave agglutination in the dilution of 8 to 32 and twenty-six serums (3.2 per cent) agglutinated in the dilution of 64 and over. The agglutination of sheep blood corpuscles was not more frequent or more marked in the serums from the vaccinated tuberculous patients and patients with positive sero-reaction to typhoid, paratyphoid B and Brucella infection than in the serums from other patients with infectious diseases, and in general no certain changes of the agglutinating ability of the blood toward sheep blood corpuscles was observed following vaccine injection against colds. Absorption tests of the serums with most pronounced agglutination in the main confirmed the value of the absorption test in the serodiagnosis of infectious mononucleosis. Examination of eighteen serums for agglutination of sheep blood corpuscles at 37° C. and 4° C., hemolysis of sheep blood corpuscles and agglutination of rabbit blood corpuscles did not afford any diagnostic information beyond that which is obtained from the agglutination and absorption tests that are usually made.

## THE PROBLEM OF THE THYMUS IN CHILDREN

A GRAEME MITCHELL, M D  
AND  
JOSEF WARKANY, M D  
CINCINNATI

The thymus gland has for a long time been a subject for study by physiologists<sup>1</sup>. It appears to many clinicians, however, that this organ is cited only when convenient to account for an otherwise inexplicable symptom, or even death. Thus the critical physician frequently wishes there were no such thing as the thymus and denies that it has any clinical implications. The thymus exists, however, and it cannot be entirely disregarded as a potential source of disturbance in early life, even though it has been too often incriminated by uncritical diagnosticians and too frequently treated by enthusiastic therapeutists. There will be considered in this presentation three ways in which the pediatrician meets the problem of the thymus, the type of encounter varying at the different stages of the child's development.

### THYMIC HYPERPLASIA

The pediatrician may be called to see a young infant suffering from such symptoms as respiratory stridor, dyspnea, cyanosis and dysphagia. Before he considers the differential diagnosis and treatment of these symptoms, two essential questions should, if possible, be answered. First, "Can thymic hyperplasia cause symptoms of compression?" The answer appears to be "Yes." Second, "Is thymic hyperplasia a frequent cause of the syndrome?" The answer is "No"—or, to paraphrase in the idiom of Chevalier Jackson,<sup>2</sup> "All is not thymus that chokes." In other words, the truth is probably to be found between the two extremes of "thymic negation" and "thymic obsession."<sup>3</sup> That some greatly respected clinicians have stated that they never encountered a stridor which could not be explained by other causes than thymic hyperplasia or that the diagnosis of enlarged thymus cannot be made during life does not prove that such an occurrence is impossible. It is a demonstrable fact at necropsy that the thymus can cause compression of the trachea, blood vessels and perhaps the recurrent laryngeal and other

nerves,<sup>4</sup> and tracheal compression has been demonstrated during life by tracheoscopic examination.<sup>5</sup>

The symptoms of stridor, dyspnea, cyanosis and dysphagia are, of course, not characteristic of thymic hyperplasia. They can be observed also in other conditions and the differential diagnosis is by no means easy.

Thymic stridor should be noticeable in inspiration as well as expiration. It should be continuous, diminishing only moderately during rest and sleep. These qualities may be of help in distinguishing it from other forms of noisy respiration. A purely inspiratory stridor may be caused by a number of more or less common conditions, such as a congenital laryngeal stridor due to softness and smallness of the infantile larynx, and may be intermittent and disappear during sleep. A loud and snoring inspiration is heard in a variety of conditions, such as retropharyngeal abscess, cysts at the base of the tongue, glossoposis and congenital macroglossia or the macroglossia of hypothyroidism. Stridor may be due also to congenital deformities or benign tumors of the larynx. In older children adenoids frequently cause noisy respiration, and deep-seated goiter is a possibility to be considered in differential diagnosis. In stenosis of the bronchioli an expiratory stridor is to be expected.

Cyanosis in thymic hyperplasia may be due to the imperfect aeration caused by tracheal stenosis or to compression of the large vessels which are situated near or, in the newborn period, even in the thymic tissue. It is hardly necessary to point out that cyanosis of the newborn may be due to a number of other causes, such as congenital heart disease, cerebral abnormalities or injuries and atelectasis, which are all much more frequent than thymic pressure.

Inspiratory retractions are not typical of thymic hyperplasia. They are found also in all other forms of obstruction of the upper and lower air passages.

Dysphagia could be caused by pressure of an enlarged thymus on the esophagus, but this type is not to be confounded with the difficulty in swallowing due to esophageal malformation or to that seen in persons with hypothyroidism or in idiotic infants.

To confirm the diagnosis of enlarged thymus, some clinicians—who, we freely acknowledge, must be more skilful than most of us—claim to be able by percussion to outline this organ. It is said to be sometimes possible to palpate the enlarged thymus in the suprasternal notch during expiration—a pleasure which has been denied to most practitioners. Lymphocytosis is of doubtful if any value in the diagnosis. It must be admitted, then, that none of the differential points men-

tioned are typical of thymic hyperplasia. Elsewhere Brown and one of us<sup>6</sup> have particularly emphasized the fact that an infant or child who has some cause for dyspnea, cough and cyanosis (as infection of the respiratory tract, congenital heart disease or the like) and who also has an enlarged thymus is more liable to these compression symptoms. Probably an enlarged thymus may aid in their production, even when in itself it would be insufficient to cause symptoms.

Roentgenograms can be helpful in the diagnosis of thymic hyperplasia. The fact that misinterpretation of these occurs all too frequently does not in itself discredit their use. Like other diagnostic tools, roentgenograms are of value only in the hands of experts who know how to use and interpret them. The discussion of this phase of the subject is better left to others in this symposium.

It follows logically from what has been stated that such symptoms as stridor, dyspnea, cyanosis and dysphagia in newborn or young infants may occasionally be caused by thymic hyperplasia. The treatment at the present time is roentgen irradiation, as first suggested by Friedlander.<sup>8</sup> Before the diagnosis is made and such treatment instituted a number of more frequent conditions must be ruled out.

Time does not permit more than the dogmatic statement that radiologic treatment is not indicated simply because the thymus appears on the roentgenogram to be enlarged. Certainly too there is nothing to support the practice of routine radiologic treatment of the thymus in every newborn infant. Furthermore, it may be stated categorically that no harm should result from one to three radiologic treatments properly given.

#### STATUS THYMICOLYMPHATICUS

Status thymicolymphaticus has nothing to do with thymic stridor. The title of Paltauf's<sup>9</sup> original paper on this subject was "On the Relation of the Thymus Gland to Sudden Death." It dealt with children and adults who had died suddenly, without preceding stridor or any other symptoms of disease. In some of these patients Paltauf saw at necropsy the following uncharacteristic symptoms: pallor, well developed deposits of subcutaneous fat, an enlarged spleen, signs of rickets and enlargement of the lymph nodes and of the thymus. There were transitional forms described by him in which rickets was not present, but otherwise the picture was similar to that in the first group. The somatic makeup of these children was termed "lymphatic constitution" and Paltauf expressed the belief that this, rather than any abnormality of the thymus itself, was the cause of death. That is to say, enlargement of the thymus was not of primary importance in this conception. Granting that there is such a condition as the lymphatic diathesis, any enlargement of the thymus would be only an indication of the abnormal constitution, and no improvement could be expected by treatment of this organ. To reduce the size of the thymus by radiologic treatment or to remove it would not be of any more value than to irradiate the spleen or some of the lymph nodes or to remove them. The situation would be similar to treating hypothyroidism by clipping the patient's dry and coarse hair, which would remove a symptom but which could hardly be considered causal treatment.

Discussion concerning status lymphaticus could be limited to these few statements. However, since the conception of "lymphatic constitution" will celebrate its fiftieth birthday next year, it might be of interest to review briefly the present attitude toward that diagnosis and its role as a cause of sudden death. Sudden death still occurs in children in whom necropsy shows enlargement of the thymus gland and spleen and numerous large lymph nodes and follicles. What should be the attitude concerning the cause of death in such cases? The studies of Hammar,<sup>10</sup> Boyd,<sup>11</sup> Greenwood and Woods,<sup>12</sup> and Young and Turnbull<sup>13</sup> have helped greatly to clarify the conception of status thymicolymphaticus. These have made it evident that the involuted thymus of the chronically sick and undernourished child had been incorrectly considered normal whereas the prominent thymic and lymphatic tissue of the healthy, well developed infant had also incorrectly been considered abnormal. In the majority of instances of sudden death in infants, well developed thymus glands and lymphoid tissues were declared abnormal because they were compared with the same tissues in children who had died after a wasting disease. In many instances of sudden death due to obvious causes such as fracture of the skull, supposedly large but obviously normal thymus glands are found. Even the mere fact that a thymus gland may weigh 20 or 30 or more grams above the average for a given age only demonstrates the wide limits of normal and is no proof that the condition of this organ was in any way related to death.

It is obvious that if status thymicolymphaticus exists not only does it comprise a great number of pathologic syndromes but it is present in many apparently healthy children.

#### THE THYMUS GLAND AS AN ENDOCRINE ORGAN

It is, of course, not possible to do justice to the problem of the thymus as an endocrine organ in a few moments. Here again are encountered the same reactions of negation and of obsession which have previously been mentioned. Thus the thymus gland was at one time supposed to have so many different secretory functions that various investigators who could not verify these assumptions experimentally came to the conclusion that it was not an endocrine gland at all. Yet some experimentally proved facts show a distinct participation of the thymus in glandular interplay—facts which cannot be overlooked by the clinician. For example, gonadectomy as well as adrenalectomy leads to delayed involution or even to hyperplasia of the thymus. This does not necessarily mean that the thymus is an endocrine organ, since many types of tissue, glandular or otherwise, can be affected by such an interference with the normal function of the organism. Removal of the thymus and administration of thymus extracts have led to contradictory results. The experiments of

Rowntree and Einhorn<sup>14</sup> will be referred to in this symposium. Briefly, these have shown that in the offspring of thymectomized rats a definite retardation of growth occurs, as reflected in body weight and in body length. Furthermore, after continuous intraperitoneal injections into rats of a thymus extract prepared by Hanson, successive generations of their offspring showed acceleration of growth and development.

When the application of these experimental studies to clinical problems is attempted, it must be recognized that we are only at the beginning of an understanding of pathologic syndromes. Suppose, for example, the clinician sees a patient who is sexually hypoplastic and who has an enlargement of the thymus. The question immediately arises whether the thymus, the gonads or the adrenal glands are primarily at fault. Some of the experiments cited previously indicate that enlargement of the thymus is secondary. Obviously, therefore, such patients would not be benefited by radiologic treatment or removal of the thymus gland or by the administration of thymic products, since these procedures would not influence the primary defect. There may be found too an apparently hyperplastic thymus in patients with pluriglandular syndromes involving the gonads, the thyroid and the adrenal and pituitary glands. According to the case and the preference of the author, any one of these glands may be placed in the center of the disease picture, the thymus usually being credited with only a secondary role. Instances<sup>15</sup> have been known, however, in which primary cancer of the thymus has apparently led to a pluriglandular syndrome and in which it might be justifiable to assume a primary role for the thymus in the symptoms caused by the endocrine imbalance. The observations of Rowntree and his co-workers could also be brought into discussion here in relation to glandular disturbances which appear in successive generations. It is to be stated that present knowledge of the possible endocrine functions of the thymus offers nothing of practical help in treatment.

#### SUMMARY

Anatomic and clinical observations support the view that an enlarged thymus gland may occasionally cause such symptoms of compression as stridor, dyspnea, cyanosis and dysphagia. These occur in many other abnormal conditions, which are more frequently operative in their causation than is disorder of the thymus. Radiologic treatment, carefully given in proper dosage, is a justifiable procedure when the thymus gland is suspected as the cause of such symptoms and when no other cause can be found. If the thymus is responsible or partly responsible for them, they should be relieved by from one to three such irradiations.

If such a condition as status thymicolymphaticus exists, and if it is in any way related to sudden death, there is no justification for the belief that radiologic treatment or extirpation of the thymus or administration of thymus extracts would have prevented such death. Abnormalities of the thymus could only be part of such a syndrome.

Present knowledge of the functions of the thymus has not led to any clinical implications which are helpful in the treatment of endocrine syndromes presumably associated with thymic abnormality. Any such abnormality would be only part of a pluriglandular syndrome.

## RADIOLOGY'S RESPONSIBILITY IN THE DIAGNOSIS AND TREATMENT OF THYMIC HYPERPLASIA

CLYDE K. HASLEY, M.D.

DETROIT

Is the present lay concept of thymic hyperplasia based on medical facts or on medical fabrications? No one can deny the statement that the general public is thymus conscious. Mothers with infants turn pale when told that cyanosis and difficulty in breathing may indicate a very slight enlargement of the thymus, and others whose infants have been treated for thymic enlargement praise and glorify Dr. Doe for his mystical and miraculous ability to detect and cure thymic disease. The public is thymus conscious, in fact, overly thymus conscious. A few legislative-minded lawyers have asked if the thymic syndrome is over or under emphasized. State supreme courts in certain instances have made and make decisions after reviewing medical facts and medical fabrications. Who is responsible for this unwarranted concern?

The unusual interest in thymic disease can be traced back to the physician, more particularly the radiologist, the pediatrician and the pathologist. In the highly specialized medical groups on radiology and pediatrics various and conflicting ideas have been expressed. One of the present debatable contentions reverts back to the time of Kopp,<sup>1</sup> in 1830, who drew attention to the fact that an enlarged thymus was present in some infants in whom sudden death had occurred during an attack of stridor and difficulty in breathing. Kopp was perhaps the first author to advance the theory that death was due to the mechanical pressure of an enlarged thymus on the trachea and the other mediastinal structures. In spite of the subsequent experimental work to the contrary, this concept of mechanical obstructive respiratory death is still accepted by a few physicians, although the majority believe that death in cases of enlarged thymus and of status lymphaticus is due to cardiac failure, and many physicians, after years of careful study, observation and research, are convinced that mechanical death never results from enlargement of the thymus. Their conclusions are based on the fact that the consistency of the largest thymus ever demonstrated was not such as to produce sufficient pressure on the cartilaginous tracheal rings to result in tracheal collapse. In spite of this evidence, however, the size of the thymus is still a controversial issue and explains, in part at least, why the lay attitude is so highly colored with medical fabrications. Before this regrettable misconception can be eliminated it will be necessary for physicians to come to some common and nonconflicting opinions regarding the part played by the thymus in sudden death.

From an anatomic standpoint the thymus is intimately associated with other structures of the mediastinum, such as the aortic arch and the superior vena cava. If one were asked to distinguish on a roentgenogram the outline of the thymus gland from that of a blood vessel, the degree of accuracy would in many cases be minimal.

Borderline thymic hyperplasia offers many pitfalls, while the much enlarged thymus is perhaps less difficult to diagnose. Too many radiologic diagnoses are made

from a single film of the chest by physicians who are not well trained in the rudiments of pulmonary radiology. No study of the chest for thymic hyperplasia is complete without a fluoroscopic study and without films made with the patient in three or four different positions and different phases of respiration and of the cardiac cycle. In the past many erroneous diagnoses of thymic

116	

hypertrophy have been made simply because the mechanics of respiration and cardiac movement were not studied sufficiently.

Donaldson<sup>2</sup> has offered a standard in centimeters for the study of thymus in newborn children. The shadow of the supracardiac mediastinum is used as a standard (normal if the shadow is two and one half times the width of the third dorsal vertebra). Measurements are made in both phases of respiration, one at the height of inspiration and the other at the height of expiration. The thymic shadow of a 5 pound (2.3 Kg.) infant, according to Donaldson's standard, can be as wide as that of a 10 or 12 pound (4.5 to 5.4 Kg.) baby.

Obviously, such a standard is open to criticism. Moreover, the thymic borders, if they can be distinguished on a roentgenogram, are not those of a fixed rigid structure with a definitely defined margin. It would seem, then, that the size of the thymus, which varies with the mediastinal shadow in the different phases of the cardiac cycle and of respiration, cannot be accepted as the actual measurement of the thymus when an incomplete roentgenographic study is made.

TABLE 2—Classification of Cases According to Age

		116	

Hasley and DeTomas<sup>3</sup> have shown that the superior cardiac-mediastinal shadow varies as much as 3 to 4 cm within ten to fifteen seconds, as recorded on serial roentgenograms made with the Jarre Cinex camera.

In the light of present knowledge regarding the mechanical movement of the mediastinum in respiration and the various phases of the cardiac cycle, a satisfactory x-ray standard for the thymic size may never be established, as so many variable mechanical factors

enter into the establishment of such a standard, such as the questions: Should the outline of the supracardiac mediastinal shadow in diastole or systole be accepted? Should it be in inspiration or in expiration? or Should it be in some intermediate phase? The inspiratory phase has been suggested by many observers.

Even though it were possible to establish a satisfactory normal standard for the size of the thymus in relation to the age, such a standard would be of but little actual value, as it overlooks the physiologic fact that the parenchyma of the gland has a secretory function which cannot be measured by size or weight. It does not hold that all thymic glands have proportionate secretory functions any more than it would hold that the thyroid glands function directly and proportionately to their size and weight. The bulk of the thymus changes too with various constitutional diseases.

It has been demonstrated in postmortem material that many of the largest thymuses have not actually been a factor in death.

Therefore the radiologic examination should not be accepted and sold to the public as the "supreme court of thymic disease."

The radiologist, of course, is interested in all phases of the physiology of the thymus which have to do with metabolism, growth, sexual development or calcium

TABLE 3—Classification of Cases According to Weight of Thymus

Weight (Gm.)	Age	Symptoms
20	6 months	Dyspnea and cyanosis 1 day

metabolism, but he is more concerned in that phase which may be in some way associated with the factors implicated in the shock mechanism of the body.

This constitutes radiology's responsibility in the diagnosis of thymic hyperplasia.

An x-ray report of thymic enlargement should not be interpreted by the pediatrician as indicating the necessity of immediate roentgen treatment. In the past many physicians have insisted that in every case in which the x-ray examination is doubtful or positive a series of roentgen treatments should be given. Such a vicious practice has discredited x-ray diagnosis and roentgen therapy. As a matter of fact, in only a small percentage of cases is roentgen therapy actually needed. Would it not be better to advise roentgen therapy when other stigmas of a lymphatic constitution are present? For it is in such cases, because of the constitutional defect, that susceptibility to shock exists.

The shock mechanism has something to do with the reaction of the smooth muscles and the response of the autonomic nervous system. The secretory function of the thymus gland may be in some way associated with this mechanism. Hammar<sup>4</sup> expressed the opinion that the functional unit of the thymus is Hassall's corpuscle while a few other authors have stated the belief that it may be the thymocyte or even the lymphocyte. Experimental work has been done with various kinds of extracts from the thymus gland some of which have

4 Hammar cited by Riesman David and Harris S. F. in Christian H. A. and Mackenzie James. Oxford Medicine. New York. Oxford University Press 1928. vol 4 p 51.

been like or similar to extracts from other lymphoid structures. It is interesting to note that in Asher's<sup>5</sup> laboratory a preparation of thymic extract was made which gave a peptide reaction. Symmers<sup>6</sup> had advanced the view that sudden death in cases of status lymphaticus is due to anaphylaxis resulting from sensitization and shock of the nucleoproteins from the necrotic germinal centers. These observations can be offered as evidence to support the theory of anaphylactic death in cases of status lymphaticus. Recently many allergists have turned to the theory of anaphylaxis expressed by Waldbott.<sup>7</sup> In fact, the late Dr. Warthin<sup>8</sup> stated that death in cases of thymus lymphaticus was due to a constitutional defect or anomaly and intimated that thymic enlargement, which was usually found in a moderate degree, was only a small part of the pathologic picture and not actually the cause of death. In this respect Warthin supported the theory which was expressed by Paltauf as early as 1890.

To further the contention that the size of the thymus gland is a somewhat incidental finding in relation to the

cause of death, the tabulated autopsy material from the Children's Hospital of Michigan<sup>9</sup> is offered. Records of 116 autopsies are included in this survey—seventy-two of males, forty-two of females and two of persons unclassified as to sex. No attempt was made to select the cases, and the study extends back over approximately eight years. In some of the cases roentgen treatment was used, but in

Fig 1—Postmortem appearance in case 1

none were diagnostic roentgenograms made just before death. Consequently it was impossible to trace the outline of the superior cardiac mediastinal shadow with the results of autopsy, but it was noted that in subsequent cases in which roentgenograms were made the x-ray appearances and the size of the supracardiac mediastinal region did not closely coincide with the conditions at autopsy. Two such cases will be discussed in detail later.

The weight of the thymus at autopsy, regardless of the age, is shown in table 1. The classification of cases according to age is given in table 2.

Among patients of 1 day or less, five deaths occurred within a few hours after birth. In only one of these was there an enlarged thymus, this weighed 36 Gm and was found in a monstrosity. All of these deaths were due to congenital heart disease and atelectasis. In the remaining nine patients listed as 1 day old cyanosis was given as the chief symptom. In two of these cases the thymus was slightly enlarged, and in all of the cases cyanosis apparently was due to a cardiac condition. In ten, or 8 per cent, of the 116 cases, the diagnosis on the basis of postmortem observations was

status lymphaticus. These cases deserve particular study. In table 3 they are classified according to thymic weight, and it should be noted that the symptoms of cyanosis and dyspnea were totally lacking or present only a relatively short time before death. In every case except one the thymus was slightly enlarged, in this it was excessively enlarged, weighing 50 Gm. Attacks of cyanosis and dyspnea had been present for a month.

The observations of this autopsy material support those of Symmers, who in 4,000 autopsies found 249 cases of status lymphaticus, of which 118 were instances of status lymphaticus proper.

Two cases observed post mortem and not included in table 3 deserve special attention. In one the thymus gland weighed 135 Gm and the right lobe was the size of an egg. There were no symptoms referable to thymic enlargement. There was leukemic infiltration of the thymus. In the second case the thymus gland was greatly enlarged, and again there were no symptoms referable to thymic enlargement. A tumor mass the size of a baseball was demonstrated. The thymus proved to be malignant, and distant metastases to the retroperitoneal lymph nodes, pancreas and kidneys were demonstrated.

To further my studies a few of the infants' chests were roentgenographed in the postero-anterior and the lateral position just before the autopsy.

The anterior wall of the chest was then removed to expose the thymus, and the thymus was measured, removed, weighed and re-measured. The corresponding roentgenograms were then traced, the heart, the superior mediastinum, the diaphragm, the lateral walls of the chest and the bony landmarks being outlined. It was found that the width of the supracardiac mediastinal shadow on the roentgenograms actually measured more than that of the dissected thymus even after generous allowance for a correcting factor, as the x-ray exposure was made at a distance of 30 inches (76 cm).

The postmortem x-ray observations in two cases are illustrated by both actual roentgenograms and animated drawings which are actual tracings of them.

Figure 1 is the postmortem roentgenogram in case 1.

Fig 2—Animated drawing made from the roentgenogram in case 1. The superimposed heavy black line represents the actual width of the thymus as found on the dissecting table.

9 Dr Martha Effie Madsen pathologist Children's Hospital of Michigan gave me permission to use the autopsy material

Figure 2 is the animated drawing for case 1. Superimposed on this is a heavy black line which represents the actual width of the thymus gland as found on the dissecting table. It will be noted that the outline of the supracardiac mediastinal shadow was approximately 9 mm wider than the black line which represents the width of the thymus. The actual weight of this thymus gland was 41 Gm, and it measured 3 cm long, 2.4 cm wide and 2 cm thick. With 12 to 15 Gm as the normal thymic weight at birth, a figure used by various anatomists, the weight of the thymic gland in this particular instance was only one third of normal, yet, with the standard that the superior mediastinal shadow should be two and one-half times the width of the third dorsal vertebra, this case would be diagnosed as showing evidence of enlargement.

Figure 3 is the postmortem roentgenogram in case 2.

Figure 4 is the animated drawing for case 2. In this case the thymus weighed 77 Gm—approximately two thirds of the normal birth weight, and again with the standard that the superior mediastinal shadow should be two and one-half times the width of the third dorsal vertebra, this case would be diagnosed as showing evidence of enlargement.

Figure 5 is the superimposition of the two animated drawings, figures 2 and 4. It is to be noted that the superior mediastinal shadow at the level of the third dorsal vertebra measures approximately the same on the two roentgenograms in spite of the fact that the one gland weighed 41 Gm and the other 77 Gm. From the x-ray examination there appears to be nothing but a slight difference in the size of the thoracic cage, which is not sufficient to indicate that one thymus gland is almost twice as heavy as the other, yet, if one should be asked to give an opinion from this single examination, as is so often done, the diagnosis of thymic hyperplasia would undoubtedly be made, whereas in reality there was marked hypoplasia in both cases.

From my studies of cases referred to in this paper roentgen therapy was indicated in only a few cases. Status lymphaticus was demonstrated in only 8 per cent and in those cases autopsy did not support the contention that the thymus actually was the cause of death. In the cases in which the thymus was largest, there were no symptoms of respiratory embarrassment. Consequently the discovery—accidental or intentional—of

thymic hypertrophy does not necessarily indicate that roentgen therapy is imperative.

During the past five years in only a few cases on which the diagnosis of thymic hypertrophy was made on x-ray examination has treatment been given, and

Fig. 4—Animated drawing made from the roentgenogram in case 2.

in spite of the decrease in treatment, as far as can be determined, so-called thymic deaths have not increased. Hence the opinion regarding the need of roentgen therapy in thymic hyperplasia is changing. It is my opinion that in only a few cases is roentgen therapy indicated and, if it is deemed advisable to try a therapeutic exposure, treatments should be given cautiously in order that there may be no delayed x-ray effects. In my experience a technic which corresponds much to that used for ordinary infection has produced the desired

result. My technic has consisted of administration in one sitting of from 40 to 80 roentgens filtered through 4 mm of aluminum, with the thyroid gland protected. This technic has been used for many years, and some cases in which treatment was given from ten to twelve years ago have been recently observed and no mental or physical retardation has been discovered. The delayed x-ray effects which have recently been reported in the literature are apparently due to overdosing. The responsibility of radiology then in the treatment of thymic hypertrophy consists of giving small, fractional, well filtered doses only in cases of extreme involvement. It is much better to err on the side of undertreatment than on the side of over treatment.

Fig. 5—Superimposition of the two animated drawings (figs 2 and 4).

#### CONCLUSIONS

1 Isn't status lymphaticus a constitutional disease in which thymic hypertrophy is of little consequence in the cause of death?

2 Isn't respiratory thymic death a myth?

3 Physicians must come to some common and non conflicting opinion regarding the standard for the diagnosis of thymic hyperplasia.

4 Physicians must come to some common and non conflicting opinion regarding the indications and contra indications for radiotherapy in thymic hypertrophy.

#### ABSTRACT OF DISCUSSION

ON PAPERS OF DRs MITCHELL AND WARKENT  
AND DR HASLEY

DR W EDWARD CHAMBERLAIN, Philadelphia. Dr Edith Boyd and I worked together and argued about the thymus back in 1922 at Stanford University Hospital, and I find her recent work and her ideas on this subject helpful. When the American Medical Association meets in San Francisco and the Sections on Radiology and on Pediatrics meet together, I find myself talking to a great many men who know what I think about thymic enlargement and its roentgen therapy. What might be the indications for roentgen therapy to the thymus? Shall it be said that x-ray evidence of a certain size of the organ is an indication for roentgen treatment? I do not feel so. In 1919 I discovered accidentally a greatly enlarged thymus. It was a little bit larger than the heart of the patient, a 1 year old infant. The accidental discovery occurred because Dr Langley Porter of San Francisco asked me to find for him a perfectly normal child at the age of 1 year with a thorax that appeared normal enough on x-ray examination to be used in his book on the young child. This child had never had a cold, had never been ill in any way and was selected for this study on her first birthday, and this tremendous enlargement of the thymus was discovered. I did not treat that thymus. However, the enlargement gradually disappeared, as was seen in subsequent films. A strange thing happened when she was 5 years old. One of the ear, nose and throat specialists of Oakland, Calif., tried to put a finger into her nasopharynx to see whether she had adenoids, and she bit his finger and he sent her to the hospital and gave an anesthetic. As soon as she had the first whiff or so of the anesthetic she became cyanotic and stopped breathing. She began to breathe again however

and is today 19 years old and in perfect health, with normal mediastinal and pulmonary shadows. Who does not know of instances in which anesthesia has resulted in such an episode and at the time x-ray study showed perhaps the slightest degree of shadow in that region? I am convinced now that there is no additional evidence to indicate that I should have treated that thymus just because the roentgenogram showed it to be enlarged. If x-ray evidence of thymic enlargement is not an indication for roentgen therapy—that is, when it exists in a symptomless child—is stertor an indication? Again I say no, because the kind of stertor that has been present in the children referred to me for roentgen therapy has not been, in my opinion, due to thymic enlargement. I have a case in which the thymus did produce stertor, and the type of stertor which was produced in this instance of definite tremendous thymic enlargement was this kind of stertor. The trachea was definitely compressed, and the ingress as well as the egress of air was interfered with. The child was kept busy trying to get air in and out past this tremendous enlargement. The cause turned out to be thymoma.

DR. EDITH BOYD, Minneapolis. As medical students, most of the members saw only a microscopic section of the thymus and learned to distinguish it from a lymph node by those queer things, Hassall's corpuscles. When I started doing autopsies of children, I discovered the thymus of the child was quite different from that of the adult. In the newborn infant the free margins of the lungs overlap two structures of equal prominence, the heart and the thymus. The thymus is attached to the pericardium and fitted closely round the innominate vein. The expanding lungs gradually mold the broad soft fetal thymus into the elongated organ of the newborn. At the same time the weight of the thymus, like that of the body, has a temporary neonatal loss. The thymus and body both double their weight by the age of 6 months. The body triples its weight by one year. The thymus does not do so before five years. Obviously, after six months the thymus will begin to be a relatively insignificant structure. A weight of 20 Gm., ordinarily considered an indication of status thymicolymphaticus, is below the average weight in the period in which thymic enlargement is supposed to occur frequently and not above the probable zone of normal variation for any age. All parenchymatous structures of the thymus increase in size after birth but are markedly reduced by maturity, while the supporting connective tissue and fat are increasing steadily in amount and variability. The cortex, which is chiefly lymphoid tissue, increases more rapidly than the medulla during early childhood, but both decrease in weight after puberty. These standards of normal age change and variation in the thymus were based on deaths, within twenty-four hours, from gross trauma and poisons. I think that the organs observed in such cases may be considered normal. In infections lasting from one to seven days, fortuitous involution reduces the thymus to such an extent that in 69 per cent of cases it is below the 25 percentile line, where it is expected in only 25 per cent, and when illness has lasted one week or more the incidence of such shrinkage reaches 94 per cent. The concept of status thymicolymphaticus arose because thymuses from persons dying of such wasting diseases as tuberculosis and gastroenteritis were considered normal while the normal prominent thymus was called pathologic.

DR. RANDOLPH G. FLOOD, San Francisco. During the last three years I have been gathering statistical data on the size of the superior mediastinum during the first twelve months of life. The data were obtained from anteroposterior orthodiagrammatic tracings, with a fluoroscope, and the superior mediastinal area as well as the total thoracic area were obtained from these tracings with a planometer. I found that I could obtain consistent measurements in this manner, provided the infant was not crying. Further, I was able to show that the fluctuations of the superior mediastinum were negligible during quiet breathing. With regard to the effect of the thymus on body build in my series of 1,124 tracings, I was under the impression that the infants who had the largest thymic area at 1 month were larger and heavier at 1 year than those with small superior mediastinal areas. To verify this I subjected 100 infants whose superior mediastinal area had been obtained at 1 month and whose weight and measurements were again taken when they reached 1 year to statistical analysis. I found that the corre-

lation between the area of the superior mediastinum at 1 month and the weight at 1 year demonstrated a correlation coefficient of 0.2815. This demonstrates a distinct tendency for those children with the relatively larger thymic areas to weigh more at 1 year.

DR. HERBERT E. COE, Seattle. In an experience covering some 2,500 operations on infants under 18 months it has been my misfortune to see six or eight of these thymic deaths. They are not anesthetic deaths and they are not due to obstruction of the respiratory tract. The outstanding characteristic is the complete absence of respiratory effort, as if there might be inhibition or paralysis of the respiratory center. I have tried all the ordinary methods of resuscitation without success. The heart beat does not vary perceptibly either in rate or in character until near the end. When artificial respiration is stopped, the color fades and the skin becomes cyanotic. The pink color may be restored for some time by renewing the artificial respiration, but there is no respiratory effort in spite of the fact that these children are in good physical condition and not infected or weak. In my groping about for an explanation of this phenomenon it has occurred to me that the involution of the thymus early in life may be significant. When an organ is no longer necessary for preservation of the individual or the species, it undergoes involution. Is it possible that one of the functions of the thymus is to inhibit respiration before birth? Is there perhaps a thymic hormone which is activated when amniotic fluid touches the pharynx? Is this the reason for the immediate cessation of respiration occasionally noted when a retropharyngeal abscess is incised? Dr. Boyd has shown that the portion of the thymus containing Hassall's corpuscles is the first to undergo involution. Are they perhaps concerned with the production of the hormone in question?

DR. HENRY F. HELMHOLZ, Rochester, Minn. It is evidently not known to what sudden death in childhood is due. However, I think that two things have been definitely decided, namely that thymic stridor must be an inspiratory and expiratory stridor and that sudden death cannot be prevented by roentgen treatment of the thymus. I think these are two important points on which to have agreed. To assume, from the medicolegal point of view, that death during or shortly after anesthesia was due to an enlarged thymus and could have been prevented by roentgen treatment of the thymus is absolutely unwarranted.

DR. CLYDE K. HASLEY, Detroit. There wasn't time to go into the responsibility of the radiologist for treatment, which is, briefly, this. If roentgen treatment is insisted on—and I think it is usually insisted on when the radiologist would believe it was not indicated—it should be given as though an infection were being treated, with from 40 to 80 roentgens, well filtered, as an average dose. It is perfectly safe to give as much as 100 roentgens if one or two treatments are given. I thank Dr. Helmholtz particularly for his conclusions, because I believe thymic death cannot be prevented by roentgen treatment.

---

**Sources of Phosphorus.**—Phosphorus is to calcium as thunder is to lightning, the two together are required to make our bones and teeth. We must have our phosphorus and plenty of it, twice as much as calcium (about 14 grams per day) for we turn over our body's total supply in less than three years. The greater need comes from the fact that phosphorus is required by some of the body proteins, phospholipins and phosphatases. Fortunately most foods are more plentiful in phosphorus than in calcium, the notable exception being milk. Meat and egg-yolk are high in phosphorus, 9 to 10 ounces of egg-yolk or 13 ounces of round steak would be sufficient for the daily supply. If you wouldn't care for 7 ounces of cocoa powder per day you could satisfy your phosphorus needs with a little less than 7 ounces of American cheese or a little more than that of dried navy beans. Infant feedings should be supplemented with egg-yolks for there are about equal amounts of calcium and phosphorus in milk and the body demands about twice as much of the latter for satisfactory growth. With this exception, however, it is generally true that if the calcium requirement is met on a mixed diet the phosphorus quota has been filled as well.—Furnas, C. C., and Furnas, S. M. *Man, Bread and Destiny*. New York: Reynal & Hitchcock, 1937.

## THE THYMUS

STUDIES OF SOME CHANGES IN THE GONADS  
AND PITUITARY FOLLOWING ITS DESTRUCTION  
BY ROENTGEN IRRADIATION

JACOB GERSHON-COHEN, M.D., D.Sc. (Mrb.)

SAMUEL S. FELS, LL.D.

DAVID R. MERANZE, M.D.

AND

THEODORE MERANZE

PHILADELPHIA

Nearly a century has elapsed since the first experimental investigation of the physiology of the thymus was reported by Restelli,<sup>1</sup> and numerous investigators have since added many data, yet the function of the thymus is still to be defined accurately. We outlined in a previous publication<sup>2</sup> the factors which we believe are responsible for the diverse opinions regarding the activity of this gland.

About two years ago we undertook to study in rats the effect of deprivation of the thymus on gastric function following roentgen therapy. We quickly recognized that striking changes occurred in the testes of the treated animals. These observations led us to a more detailed study of these effects, which constitute the chief feature of our present report.

In previous publications<sup>3</sup> we explained why we selected the rat for study and described the method and dose of roentgen therapy used; we will give here only a brief summary of our earlier results.

The exposures were made anteriorly through the superior mediastinum. Treatments were given daily and were begun when the rats were 48 hours old. The average dose was 550 roentgens and was administered on four successive days. The animals were immobilized on a board with adhesive tape. The center of the portal was determined by roentgenoscopic examination and indicated by an ink mark on the skin. The portal was from 8 to 10 mm in diameter. The rest of the animal was properly protected by a lead sheet. With this amount of radiation, atrophy of the thymus occurred rapidly and in most instances was so complete that no thymic tissue could be recognized at autopsy. We found that this could occur within ten days of treatment.

In some cases, perhaps through movement of the animal during treatment, the rays did not remain perfectly centered and incomplete atrophy of the thymus occurred. Where the residue was small, the effects on the animal were no different from those produced in other animals by complete anatomic destruction of the thymus. When more than a fourth of the gland remained, the effects of deprivation of thymus were diminished. These lessened effects seemed to occur in direct proportion to the size of the remaining thymus. These observations are of interest, especially in relation to our method of destruction of the thymus. We

previously pointed out that in the past the study of the effects of deprivation of thymus generally took place after surgical removal of the gland. We also indicated that incomplete thymectomy was followed by hypertrophy of the remaining tissue and was probably one of the most important factors in conflicting results which have been reported. Furthermore, our results indicated that complete anatomic removal of the gland was not necessary to produce the striking changes we noted. The quantitative difference found when larger portions of the gland remained was an indication that, as with all the established organs of internal secretion, the remaining portion of the gland must be below a certain minimum to cause recognizable changes. Our data also called for an opinion contrary to that expressed by Einhorn and Rowntree<sup>4</sup> that surgical thymectomy is a more satisfactory method for complete removal of the thymus than roentgen irradiation. As a matter of fact, we believe that permanent functional destruction of the thymus is easier and much more certain with the x-rays than by surgical removal.

In our previous reports we detailed changes noted in animals for the most part up to 100 days old and in a few instances up to 150 days. In treated male animals observed up to 100 days of age we saw striking changes. All observations were made on litter mates. During this period complete or nearly complete destruction of the thymus was followed by almost complete arrest of development of the testes. This was confirmed microscopically. In most instances the seminiferous tubules were represented by a single layer of marginal cells. Under these conditions it was not surprising that the animals when mated with normal females failed to procreate. We also found striking changes in the anterior pituitary in these males. At 20 days of age some difference in appearance of the anterior pituitary was noticeable when compared with that of the litter mate used as a control. This increased progressively until the rat was 100 days of age. There developed, as the animal grew older, a picture of the typical castrate pituitary, with its increase, enlargement and vacuolation of the basophils. In view of what appears to be a temporary physiologic castration, we considered the pituitary changes as secondary manifestations not directly related to the deprivation of thymus.

In the female deprivation of thymus early in life does not have any appreciable effect on the sexual apparatus. Although the thymus was destroyed just as effectively as in the male, no anatomic or functional impairment of the ovaries resulted. Microscopically no difference could be detected in a comparison with the ovaries of litter mates used as controls. The estrous cycle was not interfered with and reproduction equaled that of the controls after mating with fertile males. No microscopic changes appeared in the anterior pituitary.

Since these results were reported, we have been able to study a larger group of animals beyond the 100 day period as well as carry out numerous control experiments.

In many treated male animals by the time the 150 day period was reached, and in nearly all beyond the 200 day period, there were marked reparative changes. The testes were regenerated to a point at which it was impossible to distinguish them from those of the control animals, at mating the males were fertile. In order to establish

<sup>4</sup> Einhorn, N. H. and Rowntree, L. G. *The Biological Effects of Thymectomy.* *Endocrinology* 21: 659 (Sept.) 1937.

that regeneration really took place, we removed one testicle at 50 days from control and treated males and killed the animals at from 150 to 200 days. The testes removed at 50 days showed the striking differences between the control and the treated animal previously recorded. However, when the animals were killed at the later periods and the remaining testes examined, these differences had disappeared. The pituitaries of these animals at the time they were killed showed no appreciable differences microscopically.

These results, we believe, permit interesting speculation. The thymus in the rat reaches the peak of its growth between 85 and 100 days. Since the regeneration in the testes begins only after 100 days—a time when thymic development has normally passed its zenith—our results confirm the usual concept that its effective function is limited to the prepubertal period. During this period it appears that adequate thymic activity is necessary for the proper development of the testes. The corollary that during the prepubertal period the pituitary and adrenal glands are themselves unable to supply the necessary stimulus for proper testicular growth also seems justified. The fact that the removal of the pituitary in young animals is followed by testicular atrophy indicates that the thymic agent operates through the pituitary. We have some further indirect evidence in favor of such a mechanism. Although we were unable to show any striking anatomic or functional change in the ovary of rats whose thymus had been destroyed, recent experiences with injections of thymus extract have produced in our female animals almost continuous estrus. This too would suggest that action of the thymus on the gonads is probably by way of the pituitary.

Control experiments were performed because we realized that our experimental method—the use of x-rays to destroy the thymus—was open to criticism on the ground that our results might be due to an x-ray effect on the body generally, since we were using a fairly large dose, to an effect on the sympathetic trunks which must come in the field of treatment, or to stray radiation acting on the testes.

We were certain from the care which was taken to shield the body that stray radiation had no effect. Nevertheless, since a number of roentgenologists were still in doubt, we undertook to rule out such a possibility as well. Control experiments were done in which a similar amount of x-ray radiation was delivered over similar portals in an area below the thymus. These experiments, in which the animals were studied during the first hundred days of life, showed no difference in the testes between the treated and the control animals. Since this exposure was even closer to the testes than that delivered to the thymus, one can be certain that our previous observations were not the result of stray radiation to the testes. It is certain also that they were not purely a general x-ray effect. As the sympathetic trunks were equally exposed, damage to those trunks as an explanation of our previous results is also eliminated. The resultant data remove all doubts. In some animals we tried to give the exposures above the area of the thymus. This was found generally impossible, because in order to avoid the region of the thyroid the upper part of the thymus was usually involved, so that varying degrees of destruction of the thymus resulted in this group.

Previous experimental results concerning the role of thymic function in gonadal activity are just as conflicting as they are in the other phases of the problem.

With the discovery by Calzolari<sup>5</sup> in 1898 that the thymus continues uninvolved in animals castrated before maturity, a definite relation between the thymus and the gonads was established. This was confirmed by Henderson<sup>6</sup> and others. Paton<sup>7</sup> in 1905 concluded from studies of extirpation of the thymus in the guinea pig that the thymus inhibits the growth of the testes in immature but not in mature animals. His results coupled with those of Calzolari led him to the view that before the period of sexual maturity the thymus and sex glands act antagonistically, each exerting an inhibitory influence on the other. Adler<sup>8</sup> from studies on tadpoles and frogs came to a similar conclusion. However, in 1908 Soli<sup>9</sup> reported effects of thymectomy in rabbits, fowls and guinea pigs at variance with those reported by Paton and by Adler. He found that the removal of the thymus causes a delay in development of the testes in all three species, most marked in the cock, less in the rabbit and least in the guinea pig. He also reported analogous effects of thymectomy on the ovaries of rabbits and guinea pigs. In the testes of thymectomized puppies Hart and Nordmann<sup>10</sup> found an increase in the interstitial cells and atrophy of the sperm cells, with an absence of signs of spermatogenesis. In contrast to these conflicting positive results of thymectomy, Klose and Vogt,<sup>11</sup> Lucien and Parisot,<sup>12</sup> Pappenheimer<sup>13</sup> and Park and McClure<sup>14</sup> failed to see any changes in the testes after thymectomy.

While in our previous publication<sup>2</sup> we indicated what we believed to be the causes for the variable results regarding thymic function reported in the literature, we believe our present observations indicate another important explanation of such discrepancies. If, as our results indicate, the effect of deprivation of thymus on the testes is operative only during the prepubertal period and regeneration of such damage may occur later in life, it is not unlikely that the age of the animal at the time of observation, as well as at the time of removal or destruction of the thymus, will determine whether the results of deprivation will be positive or negative.

#### SUMMARY

Our results indicate (1) that the complete or nearly complete destruction of the thymus early in the life of the rat results in an arrest of development of the spermatogenic portion of the testes, (2) that this physiologic castration is accompanied by the development of a typical castrate pituitary picture, (3) that these changes are progressive to approximately the age of 100 days, the time when the thymus in the

rat has reached the peak of its growth, (4) that during this period all males with destruction of the thymus remain sterile, (5) that after this period reparative processes set in so that in fifty to a hundred days more the testes have completely regenerated, the pituitary has returned to its normal state and the animals are able to reproduce, (6) that similar destruction of the thymus in the female produces no recognizable functional or anatomic changes in the ovary or pituitary, (7) that control experiments prove that none of the effects seen on the testes were a pure x-ray effect, an effect of stray radiation acting directly on the testes or a result of damage to the sympathetic plexus, (8) that the thymic effect operates through the pituitary, (9) that the fact that the reparative processes are possible indicates another important explanation for the differing experimental results reported in the literature.

These regenerative results in older animals will doubtless explain too why so little damage has resulted from roentgen treatment to the thymus. Although roentgenologists in recent years have employed an x-ray dose to the thymus which certainly does not cause any secondary changes in the testes, it is possible that the exposures during the earlier days of roentgen therapy were excessive. Even in such cases roentgenologists and pediatricians need not fear that any permanent harm was done.

255 South Seventeenth Street

#### ABSTRACT OF DISCUSSION

DR EDWARD L. JENKINSON, Chicago. This work is conclusive as it applies to rats. For many years radiologists have been treating children with large thymus glands, and from my experience and from reading the literature there is apparently a marked difference in the response to irradiation by rats and by human beings. Successful and adequate treatment of enlarged thymus glands by irradiation does not call for large doses. Usually not over 100 roentgens is given to one area. It has been my practice for years to give the patient 100 roentgens over the anterior portion of the thymus and one week later give 100 roentgens over the posterior portion. Usually this amount causes a marked reduction in the size of the gland and improvement in the symptoms. If after these two treatments there has not been a definite decrease in the size of the thymus and improvement in the symptoms, the shadow is probably not due to an enlarged thymus. The treatment may be repeated in one month. Over twenty-three years I have treated a great many patients with enlarged thymus glands. I have not seen any bad effects from the irradiation. I do not recall any patient who later in life married who was not able to have children. I do not believe that the percentage of sterility in the treated patients is any higher than in the average run of men and women who have not been irradiated. I should like to ask the authors whether in the irradiation of the rats the treated area was confined to the thymus. I realize that rats are small and that it is difficult to direct the rays directly to the thymus. We all know that a good many of the tissues of infants are radiosensitive and that it is important to try to confine the treatment to the area of the thymus. I should like to inquire also as to the sensitivity of the skin of rats as compared to that of human beings. Certainly it would not be advisable to treat a child for an enlarged thymus with one erythema dose every four days, such as I understand the authors have been giving the rats. I do not believe it is necessary to treat every child who has an enlarged thymus. A great many children with an enlarged thymus present no symptoms, and in the absence of symptoms, unless the patient is to be subjected to an operation, I should hesitate to give irradiation. I am a little leery about comparing results in rats and in human beings.

The marked discrepancy in dosage must certainly be considered. I am not familiar with how well rats tolerate irradiation.

DR HENRY ULLMANN, Santa Barbara, Calif. I want to emphasize what Dr Jenkinson just said, for when the report is published plenty of internists and pediatricians will say one should not irradiate a thymus. The points to use in arguing against that are, first, that the dose is infinitely less and, second, that anything within the therapeutic range will reduce hypertrophic tonsils but will not carry them below a normal size. Now, my doses on these, as Dr Jenkinson said, are probably less, because my dose of 100 roentgens is measured on the skin. That means around 75 or 80 roentgens in the air. The other point is that the radiologist sometimes gets children sent to him by the pediatrician because they present a certain type of feeding problem. At least three pediatricians in Santa Barbara have found that that particular type, with no enlarged thymic shadow, will be definitely benefited by a few small doses over the mediastinum. Then the enlarged mediastinal shadow appears and will not go down with a few moderate doses, probably because of enlarged tracheobronchial glands. The children are benefited by longer courses such as would be used for tuberculous glands. In spite of this work, which I think is enormously valuable from the standpoint of the function of the thymus, I do not think it contains any basis for alarm in treating children for enlarged thymus or enlarged tracheobronchial glands.

DR C. K. HASLEY, Detroit. I want to discuss this paper from the angle of treatment. Dr Ullmann has already brought out the fact that the dose used for children is different from the dose used in the experimental work. At the Children's Hospital in Detroit my associates and I have made a concerted effort to follow the patients treated during the last fifteen years, we have been fortunate in following up some of them and have found that, on their return, those who have been treated with moderate doses have shown no signs of delayed mental or physical development. In the literature there have been a few cases in which it was thought there had been delayed mental and physical development because of the roentgen treatment given. Now, if that is the case, the only argument that I have to advance is that the dose was probably too large. It is not necessary to use a dose any larger than 100 roentgens. If the treatments are spaced a week apart, with the maximum number of treatments four—to get a clearing of the symptoms of difficulty in breathing and cyanosis—and if the shadow of the gland does not disappear, I think something else besides an enlarged thymus is causing it. As you know, fifteen or twenty different conditions can produce difficulty in breathing and cyanosis.

DR HARRY SHAY, Philadelphia. I think that we ought to put ourselves straight on this problem. We did not attack this problem with any idea of discrediting roentgen therapy of the thymus, we merely used it as a means of physiologically destroying the thymus. We realize that the dose employed is far in excess of that used therapeutically, and we have stressed this point in the body of our paper. The striking observation to us was that even from serious damage produced early in life we were able to see recovery. This was particularly important in the light of what happened in the presentation of some of our earlier work at the International Congress of Radiology in Chicago. At that time most of the men were perturbed by our results. We were glad to be able to show that even if in the earlier days of roentgen therapy to the thymus some temporary damage had been done, such damage was not permanent and therefore not of real moment. We realize that present day roentgen therapy of the thymus certainly cannot produce any of the damage that we have shown in our earlier pictures, but nevertheless it was essential to show that if damage did occur it was not permanent. Dr Jenkinson's question as to whether the thymus can be visualized in the small rat at 2 days of age can, I think, be answered in the affirmative. Dr Cohen, who is the roentgenologist in our group, I am sure has effectively done that, because in the animals that we show at the exhibit the area of the thymus has been pretty effectively covered by the treatment.

ESTIMATION OF DISABILITY AFTER  
INJURIES TO BONES  
AND JOINTS

WALTER G STERN, MD

CLEVELAND

With "social security" as a fixed cadastral point on the ever widening sociologic horizon, the ways and means of attaining our goal in safety are becoming of tantamount importance. Good or bad, right or wrong, such policies are here to stay and must be made actuarial, i e financial, successes if the present social system is to endure. Industrial as well as all other forms of health and accident insurance, as for instance compulsory state insurance against automobile accidents, are now considered an integral part of the social security setup, and it is here that the medical profession and particularly the orthopedists, who in recent years have been paying particular attention to injuries of bones and joints, can be of greatest service in the proper estimation of the disabilities incumbent on injury and, by that token, of the proper compensation therefor. The great importance of this subject can be best illustrated by the fact that in 1936 over 1 per cent of the entire population were seriously injured by automobile accidents alone and that the financial damage from automobile accidents in that year was estimated by the National Safety Council as over 3½ billion dollars.

After the temporary period of convalescence and rehabilitation is over—after orthopedic surgery and vocational rehabilitation have finished their work of restoring the injured person to useful industry when possible—comes the indefinite period of permanent disability, either partial or total.

Disability has been defined as "the inability to work with the same degree of ease and comfort as before the injury was sustained." Partial disability needs no further definition here, but, to be easily understood and uniform, its rating should be expressed not merely by the extent of the anatomic or functional loss but rather in percentages of permanent total disability, which was once defined by the International Association of Industrial Accident Boards and Commissions as "100 per cent unfitness for future industrial usefulness." But total disability cannot be so easily dismissed today. The "literal" rigid definition, once universal, has been modified by law and judicial interpretations until today it has come to represent something quite different. In war risk insurance, which the United States Supreme Court defined as an "unqualified insurance against total disability," in the case of *Lumbia v United States*, 290 U S 551 at 558, the court declared that total disability means "any impairment of mind or body which renders it impossible for the disabled person to continuously follow his usual work or work of like character, for remuneration commensurable with that which was paid to him in his former occupation." The Supreme Court of Texas held that "total disability" does not imply an absolute impossibility to perform any work. A person is totally disabled when his physical condition is such that he is unable to perform or direct any work without injury to his health and when common prudence would require him to desist from the performance of his duties." Arkansas and California held

"when injuries received prevent him from performing all the substantial and material acts of his business or occupation in the usual and customary way", Kentucky, "the disability is total if the insured is unable to follow his usual occupation, although he might be able to do something else", Pennsylvania, "one so far disabled as to be unfit for continuous gainful occupation and to be reduced to the status of an occasional laborer." The majority of states, however, have taken a "middle ground" somewhere between the two previous extreme positions. Their courts, however, have failed to give a clearcut definition, for the reason that their position depends more or less on the rejection of the extreme verdicts last defined. One writer has defined the limits of this position to be as follows:

(A) That the mere inability of an assured to pursue his usual, prior or customary vocation is insufficient

(B) That mere fanciful ability to engage in some occupation wholly beyond the assured's normal capabilities will not preclude recovery for total disability

(C) That the entire range of gainful pursuits is to be considered but only in the light of the assured's age, training, experience, education, as well as his physical and mental qualifications

The federal and all state governments (except of Arkansas and Mississippi) are now charged by law with the payment of compensation to injured employees, and practically all have adopted fixed schedules of percentage of loss for certain fixed disabilities, such as amputations. For instance, the complete loss of the arm at the shoulder is used as a basis for estimating such schedules, such 100 per cent loss of the arm has been variously estimated at ratings from 29 per cent of permanent total disability (New Mexico) to 56 per cent (Iowa), but the committee of the international association, already cited, recommended that a fair rating for the loss of the major arm at the shoulder by a common laborer 36 years of age would be 50 per cent of permanent total disability. This and the complete loss of the leg at the hip, also 50 per cent permanent total disability, are then the yardsticks and the schedules of percentages for other amputations and deformities have been developed from these values.

Henry<sup>1</sup> has given me permission to print the accompanying table of fixed values for partial disability (table 1).

The International Association of Industrial Accident Boards and Commissions has studied these problems for years, and its conclusions have been the guide for the revision of such schedules and have resulted in more uniform procedures. Some of its methods and conclusions are so valuable that the medical profession at large should be made familiar with them before attempting to estimate the percentage of loss resulting from disability. I shall cite a few of the most important conclusions (not verbatim, as time and space do not permit) and enter into a short discussion relative thereto.

1 Compensation paid for permanent disability is that paid after temporary disability ceases—that is, for the loss of earning power after healing has taken place.

2 Compensation for such permanent disability should be based on disability for a lifetime. (Only thirteen states allow this, others have a time or a money limitation.)

TABLE 1—Fixed Values for Partial Disability

UPPER EXTREMITY	
The upper extremity includes the shoulder girdle. Total loss of the upper extremity is usually defined by local state law. The average is 50 per cent permanent total disability.	
I Sternoclavicular joint	
(a) Ankylosis	{ rate according to resulting loss of active motion of shoulder
(b) Chronic dislocation	
II Clavicle	
(a) Complete loss	{ rate according to resulting loss of active motion of shoulder
(b) Nonunion	
(c) Malunion	
III Acromioclavicular joint	
(a) Ankylosis—as in I and II	
(b) Dislocation	
1 Incomplete (conoid and trapezoid ligaments intact)	5 per cent permanent total disability
2 Complete (conoid and trapezoid ligaments torn)	rate according to resulting loss of active motion of shoulder
IV Scapula	
(a) Malunion	{ rate according to resulting loss of motion of shoulder
(b) Loss of blade or body	
V Shoulder	
(a) Flail—40 per cent loss of extremity—which equals 20 per cent permanent total disability (unless rating for loss of motion exceeds this in which case that rating should be used)	
(b) Ankylosis—in Jones position (20 degrees in front of coronal plane 50 degrees abduction) 30 per cent permanent total disability	
(c) Ankylosis in bad position if operable 37.5 per cent permanent total disability (may be total loss of extremity if inoperable and patient is a poor operative risk)	
(d) Loss of motion	
1 Loss of elevation (useful arc normally 90 degrees from shoulder level to vertical) 17.5 per cent permanent total disability	
2 Loss of abduction (useful arc normally 90 degrees from side to shoulder level) 40 per cent arc refers to any plane and rotation is necessarily limited in proportion and covered in rating of arc loss	
VI Arm	
(a) Amputation at or above the elbow equals loss of extremity 50 per cent permanent total disability	
(b) Amputation 4 inches or more below the elbow (permitting use of elbow in prosthesis) 35 per cent permanent total disability	
(c) Shortening nil unless actually disabling or seriously disfiguring	
VII Elbow	
(a) Flail same as ankylosis in good position plus rating for loss of motion	
(b) Ankylosis in Jones position (at an angle of 110 degrees) 20 per cent permanent total disability	
(c) Ankylosis in bad position	
1 Acute angle—if inoperable total of arm if operable 60 per cent of loss of use of arm or 30 per cent permanent total disability	
2 Obtuse angle of 110 to 155 degrees 25 per cent permanent total disability	
3 Obtuse angle of 155 to 180 degrees 37.5 per cent permanent total disability	
(d) Distortion of carrying angle of elbow (15 degree valgus) 10 per cent	
(e) Loss of motion	
1 Loss of flexion beyond acute angle of 80 degrees not compensable	
2 Loss of motion (useful arc normally 80 to 175 degrees) rated on percentage loss of this range up to 37.5 per cent	
(f) 1 Loss of pronation and supination alone (in Jones position i. e. midway between pronation and supination) 10 per cent	
2 Loss of pronation and supination alone in bad position 15 per cent	
3 Loss of pronation and supination alone in Jones position when combined with disabilities of wrist or elbow an additional 10 per cent disability	
4 Loss of pronation and supination in bad position when combined with disabilities of wrist or elbow an additional 20 per cent disability	
VIII Wrist	
(a) Flail same as ankylosis in good position plus rating for loss of motion up to 37.5 per cent maximum	
(b) Ankylosis (in Jones position i. e. at an angle of 135 degrees) 12.5 per cent	
(c) Ankylosis in bad position (i. e. straight or in volar flexion) if operable 15 to 25 per cent (may be loss of hand if inoperable)	
(d) Loss of motion percentage loss of arc total loss equals 12.5 per cent permanent total disability	
1 Flexion extension disability (75 per cent of motion of wrist) 18.5 per cent loss of extremity or 9.5 per cent permanent total disability (useful arc normally is 165 degrees)	
2 Radial and ulnar abduction (25 per cent of motion of wrist) 5 per cent (useful arc is normally 30 degrees each way)	
IX Hand	
(a) Total loss 70 per cent of extremity (includes loss of arm to 4 inches [10 cm] below the elbow) or 35 per cent permanent total disability	
(b) Partial loss rated on loss of function of fingers	
1 Thumb	
(a) Total loss 20 per cent of extremity or 10 per cent permanent total disability	
(b) Ankylosis in good position (extended in apposition) 7.5 per cent permanent total disability	
(c) Ankylosis in bad position same as total loss if inoperable if operable 10 per cent	
(d) Loss of terminal phalanx 5 per cent permanent total disability	
(e) Loss of motion of metacarpophalangeal joint 7.5 per cent	
(f) Loss of motion of interphalangeal joint proportion of loss of arc of motion (normal range 90 degrees), 5 per cent	
2 Index finger	
(a) Total loss 10 per cent of extremity or 5 per cent permanent total disability	
(b) Loss of one and a half or more phalanges 5 per cent permanent total disability	
(c) Loss of terminal phalanx 2.5 per cent permanent total disability	
(d) Loss of motion or ankylosis of the interphalangeal joint	
(1) Distal joint proportion of loss of arc of motion based on 2.5 per cent	
(2) Proximal joint proportion of loss of arc of motion based on 5 per cent	
3 Middle finger (second finger)	
(a) Total loss 5 per cent permanent total disability	
(b) Other ratings same proportion of 5 per cent as in index finger	
4 Ring finger (third finger)	
(a) Total loss 5 per cent	
(b) Other ratings same proportion of 5 per cent as in index finger	
5 Little finger (fourth finger)	
(a) Total loss 2.5 per cent	
(b) Other ratings same proportion of 2.5 per cent as in index finger	
The accrued rating for loss of the use of more than one finger should not exceed the total loss of a hand as provided previously.	
Since most state laws give no definite ratings for disabilities of the spine no attempt has been made to rate the spine or the spinal portion of the pelvis. Ratings on the pelvis are covered in this schedule only and the disability limits motion of the hip shortening of the extremities or both.	
LOWER EXTREMITY	
I Thigh	
(a) Amputation	
1 Stump of less than 6 inches 100 per cent loss of leg equal to 50 per cent permanent total disability	
2 Useful stump 6 inches below hip 42.5 per cent	
3 Amputation 3 inches or more below knee (useful stump) 33 per cent	
4 Amputation in foot without loss of motion of ankle 25 per cent	
(b) Shortening*	
1 One inch no disability	
2 One to 2 inches 5 to 10 per cent permanent total disability	
3 Two to 3 inches 10 to 20 per cent permanent total disability	
4 More than 3 inches 25 to 30 per cent permanent total disability	
Just as the shoulder is considered with relation to adjoining structures in the hip motions are considered with reference to the pelvic girdle as a whole whereas scapular motion completes the upper extremity to some extent a similar relation does not play so great a part in the lower extremity, except in some fractures of the pelvis especially of the acetabulum. However the mobility of the hip is so great that the authors deemed it wise to classify these motions with specific values for each so that the total disability could be readily ascertained.	
II Hip	
(a) Ankylosis in optimum position (15 degrees flexion 10 degrees abduction and slight external rotation or a proportionate increase in abduction dependent on shortening) 50 per cent loss of extremity or 25 per cent permanent total disability	
(b) Ankylosis in bad position 30 to 50 per cent permanent total disability if inoperable	
(c) Loss of motion	
1 Flexion extension disability proportionate to loss of motion (useful arc normally 120 degrees of which flexion is 105 degrees and extension 15 degrees) total loss of motion with flexion ankylosis equals 100 per cent loss of function of limb or 50 per cent permanent total disability	
2 Abduction adduction disability (useful arc normally 90 degrees of which abduction is 45 degrees and adduction 45 degrees) total loss of abduction and adduction equals 25 per cent loss of function of limb or 12.5 per cent permanent total disability	
* The optimum position depends on the amount of shortening (Jones-Robert and Lovett R. W. Orthopedic Surgery, New York William Wood & Co 1923 table of abductions p 138)	

TABLE 1—Fixed Values for Partial Disability—Continued

LOWER EXTREMITY—Continued	
3	Internal and external rotation (useful arc normally 90 degrees of which internal rotation is 45 degrees and external rotation 45 degrees) total loss of rotation equals 10 per cent loss of function of limb or 5 per cent permanent total disability Formula The proportionate loss of flexion (25 per cent) plus the proportionate loss of abduction (12.5 per cent) plus the proportionate loss of rotation (5 per cent) equals the disability
III	Knee
(a)	Flail 40 per cent permanent total disability
(b)	Ankylosis in good position (at an angle of 170 to 150 degrees) 30 per cent
(c)	Ankylosis in bad position (at an angle of less than 140 degrees) if inoperable 40 per cent
(d)	Loss of motion
1	Flexion-extension disability (useful arc normally 180 to 75 degrees) Formula The proportionate loss of the arc (valued at 31.8 per cent permanent total disability) equals the disability
2	Extension limited to less than 160 degrees same as ankylosis in bad position
3	Abnormal lateral mobility 10 to 30 per cent depending on function
4	Relaxation of either or both crucial ligaments and other internal derangements 10 to 40 per cent permanent total disability
IV	Ankle
(a)	Flail 25 per cent permanent total disability
(b)	Ankylosis in good position 12.5 per cent
(c)	Ankylosis in bad position (equineus or over 20 degrees plantar flexion) if inoperable 25 per cent
(d)	Subastragalar ankylosis in good position 7.5 per cent
(e)	Partial ankylosis of subastragalar joints (always painful) 17 to 25 per cent if inoperable
(f)	Loss of motion
1	Dorsiflexion (valued at 12 per cent permanent total disability useful arc 90 to 70 degrees)
2	Plantar flexion (valued at 8 per cent permanent total disability useful arc 90 to 125 degrees) Formula The proportionate part of dorsiflexion (12 per cent) plus the proportionate part of plantar flexion (8 per cent) equals the disability in motion of the ankle (the proportionate loss of dorsiflexion is considered as that proportion of 12 per cent and added to the proportionate loss of plantar flexion which is represented by a total value of 8 per cent)
V	Foot
(a)	Loss of foot with loss of motion of ankle 25 per cent permanent total disability
(b)	Amputation proximal to the heads of the metatarsals (loss of weight bearing) 25 per cent In the authors experience such amputations usually require rating as for amputations above the ankle or loss of motion of the ankle
(c)	Loss of metatarsals rated as the proportionate loss of weight bearing (which if total is specified in paragraph two as 25 per cent)
(d)	Great toe
1	Amputation at metatarsophalangeal joint 5 per cent
2	Amputation at interphalangeal joint 2 per cent
3	Loss of motion (hallux rigidus) 4 per cent
(e)	Other toes
1	Total loss 1 per cent
2	Partial loss 0.5 per cent
(f)	Ankylosis between tarsal bones 5 per cent
(g)	Ankylosis of subastragaloid joint (astragalus and os calcis) 8 per cent
(h)	The frozen foot i. e. atrophied ankylosed in practically all the joints with lowered circulation a tendency to trophic changes and usually pain should be allowed the same disability as the total loss of the member i. e. 25 per cent

3 Permanent partial disability shall be valued as a percentage of permanent total disability

4 Permanent disability should be based on a table of fixed ratings, modified by important variable factors The most important of these are

(a) *Age*—A man of 60 is much more disabled by the loss of an arm than a man of 35 There are five distinct breaks in the line representing age

1 From 15 to 25 years is the experimental age, when the average boy is learning his trade

2 From 25 to 30 years shows a decided change, usually the man has learned a trade, his social status has been changed by marriage

3 From 30 to 50 years is the greatest productive age At 40 usually he starts on a decline His trade is fixed, and he is hard to adapt to a new one, accentuating any disability

4 From 50 to 60 years the aforementioned factors are even more accentuated

5 At 60 years and above age is less important The man is at the end of industrial activity

(b) *Type of Occupation*—There is a distinct and unique relation between the claimant's occupation and the amount of disability arising from a given injury The United States Veterans' Bureau uses a most comprehensive and detailed table of occupations, with a variant ratio ranging from 1 to 9, the lightest occupation usually rating the lowest The type of work must always be borne in mind For instance, a seamstress working with thin silk must be able to grasp her materials firmly with the left hand A musician with a disabled left hand can still play the cornet Disabled persons are often able to do much heavier types of work while working for themselves—and, from the nature of things, resting whenever a painful spasm arises—than they could for an unsympathetic foreman who might drive them beyond the limit of their endurance The type of light work that any individual can do is unfortunately not usually specified This leaves such partially disabled persons at the mercy of the foreman who wishes to relieve his department of the burden of keep-

ing crippled employees, and thus, in one of the cases I have in mind, light work for a partially disabled man with a crippled ankle consisted in carrying two pails full of cutting liquid at a time all day long up three flights of stairs, a task which nobody except one in the pink of health and strength could do

(c) *Presence of Pain*—Be it ever so slight, the presence of pain is a most disturbing factor and one extremely difficult to evaluate In some regions, as the shoulder and the spine, the presence of pain can be estimated by the muscular spasm which accompanies painful motion, but pain in a neighboring joint absolutely destroys any values given to the fixed disability ratings of existing deformities In partial ankylosis or fracture into or near a joint it is my belief that a stiff and painless joint is far preferable to a movable joint which produces pain Tender scars or amputation stumps add 5 per cent to the fixed disability rating

(d) *The Will to Work (morale) and Other Psychic Factors*—The mental attitude of the patient greatly influences his ability to carry out the work which his disability, age and occupation should warrant his performing Malingering and deliberate exaggeration must always be summarily condemned, but genuine psychoneurosis must at least be viewed in a sympathetic manner Some states, the latest being Iowa and Nebraska, actually pay compensation for such conditions<sup>2</sup> An examining physician must at all times be on his guard against the obvious fallacy of calling every hidden and unexplained condition a neurosis or exaggeration, and it is my opinion and constant practice never to make a diagnosis of neurosis until repeated examinations have fully demonstrated the lack of objective corroborative evidence of the actual existence of disability Often actual disability of a minor grade and psychoneurosis coexist The compensating board seeing only the cold, formal report cannot be expected to evaluate these conditions as can the observing examining physician

<sup>2</sup> Workmen's Compensation Acts Compensation for Nervous and Mental Sequelae J. A. M. A 98 1216 (April 2) 1932

(c) *Preexisting Disease or Disease Set Up as a Consequence of Injury*—Preexisting disease which has been rendered active, painful or disabling by the injury, or disease which has resulted from the trauma, must always be given due consideration and is compensable in all state and federal jurisdictions except where specifically enjoined by legislative enactment. In this regard the United States Court of Appeals has decided as follows (*General Ins. Co. v. Daffern*, 81 F. [2d] 179) "Claimant was entitled not only to compensation for disability directly caused by the accident but also for the total disability resulting from the aggravation of his preexisting ailments which prior to the operation had no disabling effects." For instance rheumatic arthropathy—Charcot joint—is sometimes seen after fractures, the first roentgenograms of which were entirely negative except for the fracture. Osteoarthritis which had hitherto been painless and symptomless can be rendered painful and disabling. I, however, do not agree with the commonly expressed opinions of Coley and Geschickter that sarcoma of bone can arise from a single injury. Neither of these authors offers any proof of

atrophy) and to pain and stiffness in the neighboring joints are not properly evaluated in the United States. The German insurance and compensating boards lay great stress on the presence of what is called in this country "traumatic tropho-edema," meaning "chronic swelling due to circulatory changes," and it has been my experience, which is well corroborated in the German literature, that this tropho-edema with swelling and stiffness of the joints may travel upward, so that an injury to the wrist, say Colles's fracture, finally results in a painful and stiff elbow and shoulder. This disability is usually recovered from and, as in atrophy of bone, physiologic use aided by the application of modern pressure-suction apparatus is the best method of cure.

(h) *Injuries to Nerves and Tendons*—Injuries to tendons are estimated according to resultant loss of function of the neighboring joints. Injuries to nerve give a combination of disabilities. These are estimated according to the loss of function in the joints involved, plus an estimated percentage for atrophy, trophic changes and pain.

TABLE 2—Percentages of Permanent Partial Disability at Various Ages

Loss of	Nature of Injury	Age Years											
		1 and Under	20	25	30	35	40	45	50	55	60	65	Over
Major arm at shoulder		40.0	47.5	44.0	50.0	52.5	55.0	60.0	65.0	72.5	80.0	87.5	90.0
Minor arm at shoulder		4.0	40.75	42.7	47.5	49.75	52.25	57.0	61.75	68.5	76.0	83.25	85.25
Major arm at or above elbow		31.0	36.12	38.25	42.5	44.75	47.75	51.0	55.25	61.25	68.0	75.25	77.25
Minor arm at or above elbow		23.0	31.75	36.75	40.75	42.4	44.4	48.4	52.49	58.4	64.6	66.61	68.61
Major hand at or above wrist		26.67	28.33	30.0	32.5	35.0	37.4	40.0	43.3	48.3	53.33	58.33	60.0
Minor hand at or above wrist		23.3	26.9	28.5	31.67	33.25	35.8	38.0	41.2	46.9	50.67	55.67	57.33
Thumb		4.0	8.0	9.0	10.0	0.7	11.0	12.0	13.0	14.0	15.0	16.0	17.0
Index finger		4.0	4.2	4.5	5.0	5.2	5.5	6.0	6.5	7.25	8.0	8.6	8.6
Middle finger		3.2	3.4	3.6	4.0	4.2	4.4	4.8	5.2	5.8	6.4	6.8	6.8
Ring finger		2.4	2.5	2.7	3.0	3.15	3.3	3.6	3.9	4.3	4.8	5.1	5.1
Little finger		2.4	2.5	2.7	3.0	3.15	3.3	3.6	3.9	4.3	4.8	5.1	5.1
Leg at hip		40.0	42.5	44.0	50.0	52.5	55.0	60.0	65.0	72.5	80.0	87.5	90.0
Leg at or above knee		11.0	36.12	38.25	42.5	44.75	47.75	51.0	55.25	61.25	68.0	75.25	77.25
Leg at or above ankle		20.0	21.25	22.5	25.0	26.25	28.0	30.0	32.5	36.25	40.0	43.25	45.0
Great toe		1.2	3.4	3.6	4.0	4.2	4.4	4.8	5.2	5.8	6.4	6.8	6.8
Other toes		0.8	0.8	0.9	1.0	1.0	1.1	1.2	1.3	1.4	1.6	1.6	1.7
Eye		16.0	17.0	18.0	20.0	21.0	22.0	24.0	26.0	29.0	32.0	35.0	36.0
Hearing one ear		4.0	4.2	4.5	5.0	5.2	5.5	6.0	6.5	7.25	8.0	8.6	8.6
Hearing both ears		26.67	28.33	30.0	32.5	35.0	37.4	40.0	43.3	48.3	53.33	58.33	60.0

this claim beyond the history of an injury. One could readily understand how an infection such as tuberculosis might crop out of a locus minoris resistencie from trauma, but how, for instance, a giant cell tumor deep in the interior of a condyle of a femur should rise from a single bruise which does not even break the tissues of the soft parts or disarrange the lamellae of the cortex is beyond my conception. My own experience contains several positive refutations of this theory, in that the tumors under suspicion were invariably secondary metastases from preexisting carcinoma, and autopsy showed widespread dissemination.

In the latest publication on this subject Ewing<sup>3</sup> of New York reviewed everything that has been published along these lines, and he came to the Scotch verdict of not proven. Leila Knox<sup>4</sup> also denied the possibility or probability of this.

(f) *Injury or Atrophy of Soft Parts*—Permanent injury or atrophy of the soft parts, when due to direct injury or circulatory change, adds from 5 to 15 per cent to the loss of function.

(g) *Circulatory Changes and Swelling*—Circulatory changes with chronic swellings which lead in great part to atrophy of bone (Sudeck's atrophy, acute transverse

(i) *Nonunion of Fractures*—Ununited fractures rate as three fourths of an amputation at the site of non union, except at the patella and the hip, where they rate as 100 per cent. Flail joints rate as three fourths loss of the joint.

(j) *Multiple Injuries*—Multiple injuries must be divided into two kinds. 1 Diverse disabilities occurring from the same trauma. These are to be computed in the same manner as are commercial discounts and not by merely adding the resulting disability values together. 2 Injuries occurring at different times. In this connection the lump sum and gross settlement plans of most states create an injustice for the insurer and unless the terminology is carefully watched, many ludicrous situations will develop. For instance, a man receives compensation for the loss of one eye and then while at work loses the sight of his second eye, receiving by the same token compensation for the loss of two eyes. In other words, a two-eyed man is compensated for the loss of three eyes. However, if the plan recommended in this paper should be followed, this person would in the first instance have received compensation for the percentage of disability arising from the loss of the sight of one eye and finally compensation for the total disability resulting from the complete loss of vision.

## ABSTRACT OF DISCUSSION

DR R W HARBAUGH, San Francisco The California Supreme Court has not defined what constitutes total and permanent disability in compensation cases. The California Industrial Accident Commission has the final duty of determining what is total and permanent disability, since the act says that the commission's decision shall be final on questions of fact. In California the standard rating for loss of the major arm at the shoulder is 60 per cent, and for loss of one leg at or above the knee, 50 per cent. California makes a distinction between major and minor in all disabilities of the upper extremities and takes into consideration the age and occupation of the injured workman. In the rating a laborer 40 years old is considered standard. If a man is less than 40 his rate of compensation decreases, if he is more than 40 it increases. If he is not a laborer but a carpenter, a structural iron worker a musician or any other type of worker, then he gets more than the common laborer, who is the lowest in the scale. The ratings are made by a specially trained expert, who has the assistance and guidance of the commission's medical examiners and medical directors, and are based on a schedule for rating permanent disabilities adopted by the commission. Neurosis is recognized as a disability in California, but the measurement of the disability in terms of its permanent effects is still an unsolved problem. No hard and fast rule can be made for compensating swelling and edema. The ratings for atrophy and neural injury are not made solely on the anatomic disabilities but on the results of the anatomic changes. The California act provides that, "in case of aggravation of any disease existing prior to such injury, compensation shall be allowed only for such proportion of the disability due to the aggravation of such prior disease as may reasonably be attributed to the injury."

DR EARL D MCBRIDE, Oklahoma City Physicians must stay with their fundamental training. They should not be biased or prejudiced or swayed by the monetary contentions of the claimant and respondent. They must stay within their own field if they are going to be on entirely safe ground. How then can a formula for evaluating permanent disability be phrased for physicians' use? I have studied this problem thoroughly, and it seems to me that the only sound scientific basis of evaluating disability is extent of function. The patient should be studied—his anatomic characteristics and the extent of ankylosis and of whatever else may have happened to him clinically. Then the physician should say to himself: "Now what can the man do with that part which is disabled?" not just "How does it differ from that same part when it was normal?" The amount of function and not the extent of anatomic change is the answer to the question of disability. Now what does function mean? If one stops to think a moment one can break that word down into a number of factors. One important factor would be quickness of action (how fast can this man work with this stiff arm?). Others would be endurance (how long can he work?), strength (how strong is he with the arm?) and security (how much confidence has he in his arm?). Also will his risk be increased or decreased as far as work is concerned? Can he pass an examination for employment? All these belong to the one word "function." Each one of those factors can be given a percentage value within 100 per cent, and if the case is analyzed according to how much each factor has depreciated the answer will be a percentage of disability based entirely on the physician's scientific analysis, clinical sense and good judgment. All the rest can be left to the jury and the courts and industrial commissions for final decision.

DR LIONEL D PRINCE, San Francisco Before one can arrive at estimates of disability after injury for the purpose of standardization throughout the United States it will be necessary to have uniform compensation laws governing the proceedings in each state. As one reviews compensation in different states there will be found great variance in the waiting period, the amount of weekly indemnity and the sums awarded for permanent total disability and partial temporary disability. In considering the estimates of disability after injuries to bones and joints one must show equal fairness to the injured and to the insurance company. A procedure that will have to be

standardized before uniform laws can be established is that of measuring joints. Frequently one examines reports by other physicians and is unable to understand their measurements of restricted motion. Some physicians in measuring angles use the ascending row of figures on the protractor, others use the descending row. Some start from different neutral points. A method of measurement should certainly be standardized. I agree with Dr Stern that the presence of pain is most disturbing and extremely difficult to evaluate. Pain is one of the greatest single disabling factors and, as stated by Dr Stern, destroys any values given to a fixed disability rating of existing deformity. A shoulder, wrist, hip, knee or ankle in which there is normal motion with pain is far more disabling than a painless stiff or partially stiff joint. Neurosis is compensable in this state. This, I think, will always be a more or less unsolved problem. Experience again counts for much in sifting the wheat from the chaff, but the problem is a real one especially when definite disability is associated with neurosis, hysteria, purposeful exaggeration and malingering. The question of preexisting injury is extremely important. No one would want to deny a man compensation if some type of preexisting disease has been aggravated by an injury. The point is: How many of these preexisting diseases are actually aggravated by injury? Frequently persons come in with arthritic backs after some trivial injury, and they attribute the disability to the injury. In private practice a large percentage of persons consult the physician because of painful backs without history of injury. From a working man one seldom, if ever, gets a history of a disability of the back which he does not attribute to his employment. The point of differentiation is a fine one and, I think, largely depends on the physician's interpretation.

DR WALTER G STERN, Cleveland This subject is a much broader one than the estimation of injury for industrial compensation alone. I told the members that the new social security schemes are here to stay and cannot be taken away from the workman even for his own good. When the money for direct relief ran out in Cleveland last fall and the city was able to beg a little more money from government agencies who wanted the families to go off relief and the men to go to work on WPA projects, over 325 men previously unknown to the Federated Charities or the Dispensary Clearing House applied in two weeks to one of the larger dispensaries alone for certification that they could not go back to work because of diverse disabilities (chiefly backache). If the funds of the various social security agencies and the various insuring bodies are to be made a "grab bag" for any claimant, the organizations are not going to be financial successes. This will cut down the amount of compensation that the injured are able to receive and will increase the premium that the employee and the employer must pay, and thus the same final conditions will appear in this country that have appeared in other countries, notably Germany, owing to the failure of the social security schemes. The plan followed by Dr McBride in his book, which I advise all interested in this subject to read, and outlined in his discussion does not really differ from mine in its final appraisal except that more of his factors are subjective and depend on uncontrollable attributes of employment which the general medical fraternity will hardly be able to evaluate. The conditions are now bad enough without having to throw in the factors of "security," "endurance," "prestige of normal physique" and the like, which are serious matters and which men of experience like Dr McBride could accurately evaluate but the rank and file of practitioners could not. It is necessary to stick strictly to the medical facts of the case, just as in noncompensable disease. A man with a stiff elbow that he cannot move more than 30 degrees is just as badly disabled in California as he would be in Ohio. The courts must be ignored because they have confused this subject so badly that from day to day one hardly knows what new medical disease will be officially declared a traumatic surgical disability. Then too they have given different interpretations of what constitutes total disability for different ends: for civil suits, for war veterans' compensation, for industrial accident compensation, for ordinary liability insurance and even in criminal cases and those involving railroad employees' pensions.

SURGERY OF GENITO-URINARY  
MALIGNANT TUMORS

HENRY G. BUGBEE, M.D.

NEW YORK

Success in the surgical management of malignant tumors in any part of the body depends on early recognition and complete removal, furthermore this is the only absolute cure for malignant conditions that is known at the present time. The application of this principle to malignant disease of the urinary tract has been especially difficult, owing to the commonly insidious onset of the disease and the impossibility of its discovery while sufficiently localized to permit of its entire elimination.

This is particularly true regarding malignant disease of the kidney. Here the earliest signs and symptoms may be long delayed in their onset, the cardinal symptoms (pain, tumor and hematuria) not being noticeable or recognized as serious until the growth is no longer confined to the kidney. The emphasis placed by urologists on the significance of painless hematuria is, however, beginning to bear fruit, and unquestionably a larger number of renal tumors are now being seen at an earlier stage of growth than was formerly the case, a second factor contributing to this result is the common employment of excretory urography.

Even with all the methods of diagnosis now available, the recognition of the presence of a renal tumor is often extremely difficult and may necessitate repeated investigations carried out at frequent intervals. The causes of filling defects to be noted in urograms, as well as distortions in the outline of the calices and renal pelvis, are many and varied and cannot always be differentiated with certainty. A blood clot in the kidney pelvis, a calculus of low density, spasm of the pelvis and calices, distortions incident to infection, tuberculosis and polycystic disease, renal torsion, displacement of the kidney, congenital anomalies and single cysts, abscess of the parenchyma or perinephric abscess, also extra-renal retroperitoneal tumors are all possibilities to be borne in mind when one is rendering an interpretation of films.

Much time and effort have been expended in attempts to classify renal tumors. From the standpoint of prognosis and possible reaction to irradiation, such a classification may be of interest and value. Scarcely any two authorities, however, agree on any one pathologic classification. The most important phase of the subject is the making of a diagnosis which will be sufficiently complete to lead to an exploration of the kidney, the one hope of cure resting on an early nephrectomy, a principle which applies to benign tumors as well.

With a diagnosis of renal tumor established there are two possible factors that may justify delay in exploring the kidney. The first is the question of employing irradiation to reduce the size of a large growth or possibly render an inoperable tumor operable (the preliminary employment of irradiation being routine in so-called Wilms tumors), the second factor is the presence of metastases. That irradiation has a field of usefulness in the treatment of renal tumors has been proved. Its preoperative use in reducing the size

of renal tumors (through apparent destruction of thin walled blood vessels with the production of hemorrhagic infarcts which may in turn destroy areas of tumor tissue) has the effect of partial removal of the tumor. Tumor cells, however, have always been found adjacent to such areas of tissue destruction.

Areas of malignancy have been found in all kidneys removed for Wilms tumors subsequent to irradiation, it would seem to be the best judgment for all such kidneys to be removed after a thorough course of irradiation. Irradiation alone must be considered as a palliative method for the treatment of renal tumors. Its employment as a routine procedure preliminary to nephrectomy is hardly justifiable in the light of our present knowledge. By so doing valuable time may be lost, during which metastasis may take place. The value of irradiation after nephrectomy seems to be still in doubt.

While it may be said that nephrectomy is seldom justified in the presence of metastases, the question of a mistake in diagnosis might well arise. This is particularly true of metastases to the lungs, which cannot always be detected with certainty. Furthermore, in certain instances metastases to the lungs have been reported to have disappeared under irradiation, so that one should not proceed according to an arbitrary rule but consider each case individually. By refusing operation in all cases showing metastases, an occasional patient might be deprived of the only possible cure.

Tumors of the renal pelvis and ureter cannot be differentiated pathologically before operation. When examinations indicate the presence of such a tumor, nephro-ureterectomy should be carried out and the mucous membrane of the bladder about the ureteral orifice should be resected or destroyed by means of diathermy.

Preliminary to nephrectomy, it is often desirable to give a blood transfusion, a pronounced anemia frequently being present sometimes caused by the presence of metastases which have not been diagnosed. In carrying out the operation it is most important to have as free an exposure of the kidney as possible. This may best be obtained by means of the transperitoneal route, the kidney pedicle being clearly exposed and ligated before the tumor is removed. With the retraction of the peritoneum however, dilated, thin walled vessels on the surface of the kidney are easily torn and the resultant hemorrhage may be difficult to control. In employing this route, lumbar drainage should be supplied by a puncture wound placed in the back. As a rule the lumbar route, especially when augmented by resection of the last rib or employment of a transverse incision with a prolongation upward in the midline anteriorly, will give sufficient exposure. If it is thought necessary to remove the ureter, the lumbar route is to be preferred, furthermore, in the instance of tumors of the renal pelvis the kidney seldom reaches large size. Injuries to the bowel, vena cava and pleura are possible during nephrectomy for renal tumor and are best avoided by employing a free exposure. Extension of the growth into the renal vein or vena cava has been noted.

There have been fifty-four renal malignant growths under treatment at St. Luke's Hospital during the past ten years. Of this number twenty-nine were diagnosed as hypernephroma, one being bilateral. In eighteen metastases were present. Of eleven patients without metastases who were operated on, four are alive ten

five, three and two years after operation. There were fourteen patients with carcinoma of the kidney (seven showing metastasis). Of this group two are alive six and three years after operation. Of five patients with carcinoma of the renal pelvis, one involving the ureter, two patients are alive three and two years after operation. I have a third patient in the latter group alive twelve years after operation. Three patients with sarcoma of the kidney all died within two months. There were also two patients with adenoma, both alive, and one with epithelioma.

This brief summary of cases indicates (1) that the large majority of cases of malignant disease of the kidney are seen late in the disease, when metastases are present, (2) that, in the cases seen before metastases are present, nephrectomy offers a distinct hope for a cure. In one case in which nephrectomy was attempted and found impossible, irradiation reduced the growth to one-third the original size and I was able subsequently to remove the entire tumor. The pathologic diagnosis in this case was carcinoma of the kidney.

A greater difference of opinion exists regarding the treatment of bladder tumors than of any other type of malignant condition of the urinary tract. Before the advent of fulguration and irradiation, no treatment other than surgery was known. The end results from surgery were so poor that any new method of procedure was welcomed.

The common types of tumors of the bladder are papilloma, papillary carcinoma and infiltrating carcinoma, other types of malignant growths are so rare that they will not be considered in this brief discussion. While pathologists are not in entire agreement as regards the classification and gradation of malignant tumors of the bladder, Broder's gradation (based on the percentage of cells fully differentiated into adult forms) seems to be the most satisfactory one yet given. The question always arises as to whether the biopsy specimen represents the character of the entire tumor, with the tendency of so-called benign papillomas to recur, the recurrences often showing definite malignancy, it is a question whether apparently benign papillomas of the bladder should not be considered as grade 1 malignant growths.

That all tumors of the bladder should be thrown into definite classes, depending on the gradation of malignancy, and each class be treated as a routine, does not seem to be good judgment. The appearance of the growth, its position and size, mean much to the eye of the trained cystoscopist. The age and general condition of the patient and the question of metastases must also enter into the decision as to the line of procedure to be adopted in individual cases. All will agree that so-called benign papillomas or papillomas of a low grade of malignancy should be thoroughly and completely destroyed by fulguration. The resectoscope is often of great assistance in carrying out this procedure, especially when large and multiple papillomas are present. Equally important is a follow-up, cystoscopic examinations should be made at regular intervals for an indefinite length of time, the intervals becoming less frequent with the lapse of time should no recurrences appear. Recurrences should be recognized promptly and immediately destroyed.

Papillary carcinoma presents a different problem. Surgical resection has given good results in certain cases, while in others recurrences have occurred promptly. A definite pedicle seemingly surrounded by

an area of healthy bladder wall, when removed has often shown, on microscopic section, chains of cancer cells extending along the muscle bundles, even to the cut edge of the bladder mucosa. In other instances a supposedly pedunculated growth has proved to be the apex of a tumor, the broad base being situated in the outer layer of the bladder wall or in an extravescical mass of large size. Tumors are often multiple and are frequently situated in close proximity to a ureteral orifice, necessitating ureteral transplantation if the bladder wall is to be resected, a procedure which may result in a functionless kidney. With the advent of radium, the implantation of seeds into these growths or into the base of the pedicle after destroying the papilloma became a common practice. The difficulty of an even distribution of radiation following the introduction of seeds containing radium element or emanation, the destruction of intervening normal tissue, local irritation and burns resulting from its use, as well as the general toxemia that was produced, have resulted of late in its less frequent employment. Diathermy has been employed through an open bladder with seemingly satisfactory results in certain cases, and more recently transurethral resection has often proved to be a satisfactory method of removal of this type of growth. Within the past six years transurethral resection has been employed in eighteen cases of papillary carcinoma, and the results in these cases to date have been more satisfactory than those obtained by any other single method of treatment. The pedicle must be thoroughly destroyed, irradiation may be employed in conjunction with resection, and follow-ups are essential. Recurrences frequently present a lower degree of malignancy and often are more easily destroyed than was the original growth.

Infiltrating carcinoma of the bladder has been subjected to the same variety of procedures as has papillary carcinoma. In this type of tumor, especially when located in the trigon, the question of the advisability of a total cystectomy with deviation of the urinary stream will arise in an occasional case. This operation, while radical, must nevertheless be undertaken before the growth has extended beyond the bladder or metastasis has taken place. It will necessarily have a limited field of application.

Tumors of the bladder show such variations in structure, rapidity of growth and vulnerability that it is difficult to compare the efficacy of different methods of treatment. Irradiation in the form of radium or high voltage roentgen therapy may have a definite effect on certain papillomas, but such growths may also be readily destroyed by fulguration or removed with the resectoscope. Irradiation is frequently employed in cases considered hopeless in the light of other methods of treatment, yet infiltrating carcinomas are more or less definitely radioresistant. Certain tumors increase in size slowly, even if no treatment is applied, and such growths are undoubtedly those which seemingly respond well to various methods of treatment.

In reviewing 139 cases (thirty-one of which were reported pathologically as papillary carcinoma and 108 as carcinoma of the bladder) treated in St. Luke's Hospital during the past ten years, I found that one patient was alive five years after high voltage roentgen therapy only, five were alive after radium implantation two, three, four, six and in one instance seven years after treatment, four patients were alive five, four and three years after surgical resection, one patient was alive fifteen years after surgical resection and radium,

four were alive after fulguration (one of twenty, one of ten and two of eight years' standing) while patients are living the following number of years after transurethral resection of the growth: one six years, three five years, four four years, seven three years, four two years and three one year.

Twenty-two patients of the entire series presented extensive metastasis when first observed. Thirty-four patients are known to be alive three years or more since they were first seen. Excluding the twenty-two patients with metastases and inoperable conditions, 31.4 per cent are alive and well three years or more after onset.

There has been no question that the results obtained in cases of papillary carcinoma over a period of five years during which transurethral resection has been frequently employed have been better than those obtained by irradiation or surgical resection only. This has not precluded, however, the employment of any type of procedure or combination of therapy that seemed advisable in individual cases. More time must elapse before it will be possible to determine the number of actual cures as well as the lengthening of life that may be expected following such treatment. Obviously one cannot hope to remove entirely an infiltrating carcinoma involving the entire thickness of the bladder wall by transurethral resection, nor can one derive much encouragement from efforts to eliminate such growths by open operation or irradiation. A modified technic for applying irradiation, such as roentgen therapy to the open bladder, may in itself or in combination with surgery or resection prove to be a step forward. Many patients with malignant tumor of the bladder still come to us in the late stages of the disease, when all treatment must be palliative in nature, yet a diagnosis of tumor of the bladder is seldom difficult to make.

Rarely is the diagnosis of carcinoma of the prostate made at a stage of the disease sufficiently early to permit of removing the entire growth. Only by the removal of the entire prostate and its capsule can one effect a cure for prostatic cancer. Cancer may originate in association with hypertrophy, it may arise in the posterior lobe or in the perineurethral glands. It is present in approximately 20 per cent of all cases of prostatism and is discovered on microscopic section in approximately 3 per cent of prostates removed for hypertrophy. Arising commonly in the posterior lobe, cancer of the prostate frequently invades the seminal vesicles by direct extension, often involving the neck of the bladder and becoming a sizable growth before retention or hematuria occurs. In other words, a sudden attack of retention or the appearance of blood at the end of urination may be the first indication of what on examination will prove to be a growth that has already involved the prostatic capsule and seminal vesicles, the gland then being hard, nodular and firmly fixed.

Cancer of the prostate is often slow in growing. Patients have been observed over long periods (in one instance twelve years) during which little change has taken place in the size of the growth and there has been no appreciable interference with urinary function. It is undoubtedly in this type of case that various methods of treatment have given encouragement as to the results obtained, from either surgery, irradiation or transurethral resection, or combinations of any or all of these procedures.

In 1936 I reviewed cases of carcinoma of the prostate observed over a period of twenty-five years and

in which prostatectomy, cystostomy, irradiation and transurethral resection were the treatments used. At that time a series of sixty-three resections carried out on fifty-two patients during the previous four years were cited and the technic employed in transurethral resection was described. During the past two years, twenty-four additional patients have undergone this procedure for cancer of the prostate, in four instances carcinoma of the bladder was also found to be present and was completely removed by resection at the same time.

The results have continued to be such that except in the occasional rare case in which an entirely encapsulated growth may be completely removed or it may seem wise to employ irradiation transurethral resection by restoring bladder function even in the presence of metastases has given more relief and for a longer period than has any other method of procedure employed up to the present time. High voltage roentgen therapy may be beneficial in relieving pain incident to metastases.

Two patients treated with radium only have survived seventeen and fifteen years after prostatectomy, two patients are alive fourteen and eleven years after operation while of seventy-six who have had transurethral resections with no operative mortality thirty-nine are known to be alive and comparatively comfortable over a period of from one month to six years after operation.

#### SUMMARY

A malignant condition of the urinary tract whether located in the kidney, ureter, bladder or prostate, can be cured only by its complete removal while still localized. This can be effected only through an early diagnosis which may be difficult because of the late appearance of physical signs and symptoms suggesting its presence.

Irradiation in the instance of kidney tumors may be a valuable adjunct but does not take the place of surgery.

Nephrectomy carried out under satisfactory exposure and with as little traumatism as possible will result in a certain number of cures. Cancer of the kidney pelvis and ureter (the latter to be suspected in all instances of filling defects in the ureterogram) should be diagnosed early and a nephro-ureterectomy carried out.

Tumors of the bladder, while easily diagnosed, are often allowed to become extensive before being discovered. Fulguration and transurethral resection give excellent results in low grade papillomas and in certain cases of papillary carcinoma, while infiltrating carcinoma is often radioresistant, and the only surgery applicable may be a total cystectomy following a deviation of the urinary stream.

Cancer of the prostate is essentially a fatal disease. Rarely is its complete removal possible. As a rule when the diagnosis is made the disease has extended beyond the capsule, and one's efforts may best be expended in restoring urinary function, which may be accomplished with a minimum of risk to the patient by means of transurethral resection, it being borne in mind that most cancers of the prostate are slow in growing.

A certain amount of encouragement should be derived from the occasional cures obtained from radical surgery in all types of malignant conditions of the urinary tract, also from complete eradication of tumors of the bladder, in some instances by fulguration and by means of the resectoscope. Transurethral resection has proved to be a decided addition to our methods for treating

cancer of the prostate—at least to the extent of giving functional relief without mutilation

The watchword should be “early diagnosis,” with constant emphasis on the necessity of ascertaining the origin of red blood cells in the urine, for only through such means will one be able, in the light of our present knowledge, to substitute methods of cure for palliative treatment in the management of genito-urinary malignant tumors

2 East Fifty-Fourth Street

#### ABSTRACT OF DISCUSSION

DR GEORGE C PRATHER, Boston Regarding malignant tumors of the testis, less importance should be attached today to the hormonal diagnostic tests than was believed warranted three or four years ago, unless a quantitative report can be obtained from a dependable laboratory. It is to be hoped that further observations resulting in a more definite yardstick for measurement of the follicular changes which the hormone causes will eventually be a definite aid in diagnosis and prognosis. In the treatment of a testicular tumor I prefer preoperative fractional irradiation of the affected part and bony pelvis followed by orchiectomy, by the technic of ligating and bisecting the spermatic cord before delivering and removing the testicle. There are times, however, when all diagnostic methods may leave one uncertain as to whether the patient has a testicular tumor or other scrotal abnormality. In such an instance I hesitate to use radiation, even as a therapeutic test, preferring to inspect the testis through a gently made but generous incision in the cavity of the tunica vaginalis, which allows adequate exposure with a minimum of handling of the testicle, should the trouble be tumor. One has, of course, another choice when the preoperative diagnosis of testicular tumor is uncertain—that of performing orchidectomy after ligation of the cord. This, however, may lead occasionally to an unnecessary sacrifice of a valuable structure. It is agreed I believe, that testicular biopsy should never be done except by orchidectomy. My lack of experience with Hinman's courageous operation precludes any remark. No doubt the greatest improvement in the percentage of five year cures in persons with malignant tumors of the renal cortex will, during the next few years, occur in children having the Wilms type of tumor. This success will be due in a great part to the miraculous recession in size caused by the fractional or Coutard type of irradiation preliminary to nephrectomy, a procedure now generally accepted. The death of many, if not all, tumor cells as the result of radiation in the kidney with Wilms tumor makes nephrectomy relatively safe, from the standpoint both of immediate mortality and of spread of malignancy during operation. Unfortunately the response of malignant tumors of the renal cortex in adults to preoperative roentgen treatment produces only moderate, if any, appreciable recession in size of the tumor, so that one is often faced with nephrectomy for a patient showing a large renal tumor with no demonstrable metastases. If my logic is correct in the technic of orchiectomy for malignant testis, one should do transperitoneal nephrectomy, ligating the renal pedicle before attempting to deliver the kidney. There are times, however, when a tumor originating on the anterior surface of the kidney close to the hilus causes delay or difficulty in exposing the pedicle. Exploration of a kidney where there is only a question of tumor should, I believe, be done through an extraperitoneal incision of the flank.

DR CLARK M JOHNSON, San Francisco Dr Bugbee has reviewed a subject to which a lifetime could be devoted. He has outlined the treatment of cancer of the kidney bladder and prostate and indicated his preference. He has stressed the key to the only cure known for cancer—early diagnosis. He has not attempted to regale the members with cures due alone to irradiation or to radical surgical measures. I wish to emphasize the importance of the subject he has presented. In ten years at the University of California Hospital there were 4,592 admissions in the urologic service. A definite diagnosis of cancer of the genito-urinary system was made in 274 cases. Of this number many were reentries, I was unable to separate the

reentries from new cases. The number of cases of cancer included only those in which the diagnosis was proved by a pathologic examination. However, the 6 per cent or more of cancer in a urologic service gives it importance. When I find that of the 274 patients with malignant growth only a small number are still alive, the number assumes added importance. The patients had the advantage of as good high voltage roentgen therapy with or without radical or palliative surgical measures as there is available, to my knowledge. The poor results, therefore, were due to late diagnosis, and results will be the same in a similar group of patients until there is available a real cure for cancer in all its stages or a more concerted effort is made by the whole profession and the public which will lead to earlier diagnosis. This is particularly true of cancer of the bladder, hence I have singled out seventy-six cases of that condition. These represent the worst possible results because only hospitalized patients are in this group. About 150 cases of papilloma of the bladder were observed, and a fair number of these were labeled by the pathologist as instances of papillary carcinoma or malignant papilloma from the biopsies. It was in this group of precancerous lesions or early cancer without deep infiltration that cure was obtained. With carcinoma of the bladder advanced enough to require hospitalization there was a history of hematuria and urinary symptoms of months or years before examination. Sixteen patients were lost track of. Of the other sixty, only four are known to be alive. All four underwent cystectomy and diversion of the urinary stream. Many of the others died of urosepsis, without definite evidence of recurrence of carcinoma. Too often the justifiable energetic treatment of carcinoma of the bladder is undertaken without enough regard for the upper part of the urinary tract, with resultant ureteral stenosis and death from uremia.

#### FACIAL DISFIGUREMENT AND PERSONALITY

WILLIAM Y BAKER, MD

SEATTLE

AND

LAUREN H SMITH, MD

PHILADELPHIA

With the rapid advance of reconstruction surgery during the past decade in technic, in availability to the public and in the types of disfigurement that have been treated, new interest has developed in this field. The experience of surgeons has been, however, that the benefit derived is not always in keeping with the results. They have found patients who have benefited both in body and in mind but also patients who, although they have experienced very creditable surgical results, have remained unsatisfied and have shown that they are sick and maladjusted persons.

A study was undertaken of the personality of patients coming to the Graduate Hospital of the University of Pennsylvania for plastic repair of facial disfigurement under the direction of Dr Robert H Ivy and his associates. There has been a total of 312 such patients. In this study, patients with disfigurements of recent traumatic origin were not included, for the reason that the immediate reaction to an accident is determined by the existing personality. Only after from two to five years should one take as permanent the effect of facial change, because this time is necessary for the personality to accept and incorporate the new factor.

Twelve cases were taken as examples for detailed study. The study was carried out in the Graduate Hospital, usually during the postoperative period, when operation was performed and at the Institute of the Pennsylvania Hospital when the disfigurement was not suitable for surgical intervention or there was special psychiatric interest.

The patients were interviewed informally on from two to six occasions, each interview lasting from two to eight hours. They were not conscious of the reason for these interviews. After a general history had been obtained, the personality material was elicited in an informal manner, the latter was later incorporated into workable form, the outlines of Strecker and Appel being followed.

A brief summary of the twelve cases gives some indication of the contrasts on which their separation into three groups is justified.

**CASE 1 (group 1)**—A boy aged 13 had burns of the neck and face, with contracture, of ten years' duration. He was an athletic, intelligent, artistic boy in the tenth grade. His health had always been good, and he had a cheerful, happy, optimistic personality, was socially inclined and outgoing, possessed no inferiority complex and no self-consciousness and was rather phlegmatic. He came from a demonstrative family, was rather close to his parents in affection and had no jealousies of his siblings. He accepted his handicap rather well and was objective about it.

**CASE 2 (group 1)**—A rather phlegmatic, psychic girl aged 16 appeared at the clinic for repair of contractures of the neck and shoulder occasioned by a burn which she suffered at the age of 6 years. Her reason for wanting an operation was that she wanted to get married and be better looking. There was no sense of inferiority, she stood pain well and her energy was quick and steady. She was rather cheerful, friendly and sociable, having no especial drives or ambitions. She was close to her mother and spoiled because of her burns. However, there was no jealousy of her siblings. Her amusements were outgoing. She admired her sister. Her interests were marriage and family. One suspected a low intellectual capacity. This girl had not been affected by her handicap, did not expect too much from operation and was expected to make a satisfactory adjustment after repair.

**CASE 3 (group 1)**—A man aged 29, an Assyrion, came to the clinic to have a long, redundant tip removed from his nose, saying "It keeps me from advancement in my work, my boss has told me so." He had a trade school education, had been in excellent health, lived with his family and had made a good social adjustment in spite of his congenital facial appearance. He had advanced in his trade and was friendly, outgoing, tactful, neat and efficient. He was affectionate and took close care of his mother and siblings. He was an artistic, social type, his ambitions were well within the realm of possibility and he dealt objectively with his handicap. He did not expect too much from operation.

**CASE 4 (group 1)**—A man aged 27 came to the clinic with hemiatrophy of the face and progressive ankylosis of the jaw, which began at the age of 7, after an infection. He wanted the operation so that he could eat. He was a cabinet maker, provided for a large family and had made a good social adjustment. There was no inferiority despite marked deformity. He was emotional, cheerful, optimistic and objective, he adapted well and had no more than average anxiety. He was decisive and neat and expected little from operation that could not be given. He had a healthy concept of his condition, and after operation the results were good.

**CASE 5 (group 2)**—A white woman aged 23 had had post-infective hemiatrophy of the face and skull with ankylosis of the jaw for seventeen years. She wanted an operation so that she "could become more acceptable to people and get a job." She had a tenth grade education, her health was poor as a child and she had been dependent on her family throughout her life. For the past ten years she had withdrawn into her home, keeping away from all social contacts. She was moody, explosive, childish and resentful, with marked likes and dislikes. Her ambition was to become a nurse in a home for the blind or with crippled children or to be a beauty operator. She expected operation to make her an average, acceptable face and was vindictive and depressed when she found that this could not be done. After operation she became quite a problem for a while because of her attempts to compensate.

**CASE 6 (group 2)**—A woman aged 24 came to the clinic for repair of a cleft palate and a harelip, on which there had been an unsuccessful attempt at repair ten years before. She came because of her "facial appearance." She had a business college education, although she refused to graduate because of a slighting remark made by a professor. Her health was good, although she was dependent, complained of pain and was easily hurt physically and emotionally. She fatigued easily and was irritable, tense and excitable, cynical and self-conscious. She desired attention and was subborn and childish, with an ego-centric, vindictive trend. Her family relationships were completely demanding and egocentric. She hated her mother and sisters because, she said "They are so beautiful and don't realize what I go through." After repair of her harelip was successful, a hysterical paralysis of one leg and alleged phlebitis developed, and it was only with difficulty that she was discharged from the hospital. She very evidently was hiding behind her deficiency and other psychoneurotic symptoms quickly developed to replace her harelip when it was repaired.

**CASE 7 (group 2)**—A psychic German youth aged 23 came to the clinic for repair of a post-traumatic scar on the right side of the face with a contraction deformity of the nose and eyelid of five years' duration. He wanted the repair because he wished to get married. He had a tenth grade education, stood pain well and was self-conscious, seclusive, irritable, embarrassed, reticent and somewhat suspicious. He projected much of his social trouble onto the accident and had no close emotional ties either at home or with friends. He felt that he had not received adequate restitution for his accident and was vindictive. He was prone to lay much of his financial and social difficulty to the deformity and was expected to react only moderately well to operation.

**CASE 8 (group 2)**—A man aged 41, who came to the clinic with a congenital saddle nose, desired repair so that he would "be a success in business and marital life." He was a photographer, his health had been good, he had marked feelings of inferiority concerning his facial appearance and on this placed the blame for his inability to make a good living in his chosen field and also for the marital infidelities of his wife. He was tense, envious, moody, irritable and unstable. Socially he was apologetic and withdrawing, undecisive and easily hurt. He was dominated by his wife and felt inferior to all about him. He felt definitely that his facial appearance was the cause of his business failure and expected repair of his nose to alleviate all his difficulties. He was not objective in his attitude toward operation.

**CASE 9 (group 2)**—A man aged 35, a Jew, asked for remodeling of his racial nose because his nose kept him "from getting a job or joining social clubs." He had had two years of college education and his health had been good, although he complained continually and felt markedly inferior to those about him. He fatigued easily and was indecisive, fearful and slow thinking. He came from a family background of strife, parental separation and parental domination. He was childish and immature in his attitude toward his family and his own importance. He had never had a job, had no ambitions or goals and was completely bound up in the problems of the moment. His was a completely inadequate personality. He blamed his racial heritage for his inability to find happiness. No operation was performed because of this quite evident rationalization.

**CASE 10 (group 3)**—A man aged 30, a German, with a post-traumatic asymmetry of the mandible, asked for repair so that he could "go out of the house in the daytime and not be laughed at." In reality, the examiner had to ask what the deformity was before it was noticeable. The patient had quit many jobs and had been unable to continue work until he got a job in a mine where he would not come in contact with other people. He was seclusive, antagonistic and resentful, blaming others for his misfortunes. He was dependent on his wife and jealous of his friends and relations. He was hypochondriacal and prone to blame his environment for his troubles. After operation there developed a transitory amaurosis, which responded to suggestion. He became demanding and antagonistic in the ward, although the surgical results were excellent. This man will probably remain a chore to the surgeon or to the medical staff.

CASE 11 (group 3)—A fair-skinned, retiring, reticent, Irish youth aged 19 came to the clinic for removal of a small, soft, postoperative scar at the hairline of the left brow. It had been present for four years. He said "It keeps me from making friends, people look at it and laugh and I am embarrassed." The deformity had to be pointed out to the examiner. The patient's father had been an alcohol addict, and his mother, who was tuberculous, had died when he was 10 years of age. He grew up in an atmosphere of constant strife and uncertainty and was adopted at the age of 13. He went into the navy "to become a man," was disappointed in his advancement and in the past year had become seclusive, unhappy and suspicious. He blamed the small scar for his inability to find social success. His was an introverted personality rationalized on the basis of a small scar. No operation was performed.

CASE 12 (group 3)—A girl aged 17 was operated on at the age of 13 for "lop ears," as she felt that they prevented her from entering social activities and making friends. Since the operation there had been a recurrence of physical and emotional upsets. She was withdrawing, asocial, egocentric, suspicious and immature. She hated her sisters and mother and had tried to kill them. She had no capacity for ideals or ambitions and was completely self indulgent and egocentric. A diagnosis of schizophrenia was made, and she was committed.

From a study of these cases we feel that persons with facial disfigurements can be divided into three main groups. Group 1, the superior group, consists of well adjusted persons (cases 1, 2, 3, 4). Group 2 consists of persons with recessive or inadequate personalities, who retreat behind the "handicap" and unconsciously use it as a defense (cases 5, 6, 7, 8). Group 3 consists of prepsychotic and psychotic persons, with whom the facial abnormality is the material, the factual point of focus, of a schizophrenic process (cases 9, 10, 11, 12).

In the first of these groups one finds moderately successful, well adjusted persons who have marked disfigurements and who wish repair purely for cosmetic reasons or for comfort and not as an answer to all their problems, financial, emotional and social. They do not expect too much of their improvement and have a logical concept of the outcome. They offer ideal material for obtaining successful results, both plastic and emotional.

A report in greater detail of case 4 illustrates well this type of patient.

An Italian cabinet maker had infantile paralysis at the age of 7 and an abscess at the age of 14 which produced hemiatrophy of the face and progressive ankylosis of the jaw. At the age of 20 he was able to open his mouth only half way. When he came to the clinic he could open it only 2 cm. He had felt no especial handicap from his facial appearance, was a leader in social activities, had succeeded in his trade, was happily married and was supporting a family of four. His only worry was the loss of time occasioned by the operation. He had accepted his facial deformity and adjusted himself well. He was excellent personality material and characteristic of the group in which one would expect the best plastic results.

The recessive, or inadequate, personality group is composed of those patients who, feeling a marked handicap because of their condition, have secluded themselves and altered all their desires, emotions and activities because of their facial appearance. They have become limited in their social scope, general knowledge and social experience. They tend to develop a jealous, hateful personality indicated by sarcasm, a cynical attitude, marked aggressive hates or loves, dislike of siblings or parents and active hate and envy more or less repressed, for "normal people." These feelings may be repressed to below the conscious level. An exposing of them is a greater surprise to the patient than to the

people in his environment. The ultimate result may be expressed as marked antisocial activity or sadistic desires. Because of or as part of the typical seclusive life these people lead, their emotional development remains at an egocentric, immature and childish level, making them selfish, self indulgent, self deifying, thoughtless of others, obstinate, and illogical in matters pertaining to their own comfort or activities. Their attitude is usually quite easily controlled by suggestion and tactful persuasion. Their immaturity makes them fearful, prone to panic states, suspicious and deceitful. It is the basis for their self consciousness, ideas of reference, easily hurt feelings and projection of their difficulties onto the environment.

The result of this immaturity and fear, which produce a vicious cycle, is often laid at the door of the facial disfigurement by the patient.

What is the result of the removal of this answer to his personality inadequacy, is the surgical repair of the facial anomaly?

For years the scar, harelip or misshapen nose has been looked on as a handicap, and its importance in the social and emotional adjustment is unconsciously all embracing. It is the "hook" on which the patient has hung all inadequacies, all dissatisfactions, all procrastinations and all unpleasant duties of social life, and he has come to depend on it not only as a reasonable escape from competition but as a protection from social responsibility.

When one removes this factor by surgical repair, the patient is cast adrift from the more or less acceptable emotional protection it has offered and soon he finds, to his surprise and discomfort, that life is not all smooth sailing even for those with unblemished, "ordinary" faces. He is unprepared to cope with this situation without the support of a "handicap," and he may turn to the less simple, but similar, protection of the behavior patterns of neurasthenia, hysterical conversion, hypochondriasis or the acute anxiety states.

It is this group which forms the exasperating, disturbing chore for the surgeon who has obtained an excellent technical result. Such patients make the surgeon realize that his responsibility includes "the person" as well as the operative field. Because of this, psychiatric aspects must be considered by the surgeon in working for complete and satisfactory results. It is the duty of the psychiatric service to aid the surgeon in helping to spot such potential reactions.

Case 5, here presented in greater detail, is an example of this group.

An unmarried young woman had hemiatrophy of the face and skull to the left with resulting ankylosis of the jaw. This was occasioned by recurrent osteomyelitis at the age of 7 to 12. She went to the tenth grade in school and then quit and withdrew into her home because her facial appearance "made people laugh." She had had no social contact for the past ten years and her admission to the hospital was the first time she had been away from home during her entire life. She said "I thought I would come to the hospital and go out with a beautiful face like every one else." After the first operation she realized that this would not happen, became depressed and threatened suicide in a childish fashion. She was stubborn, obstinate, sensitive and suspicious. She had quick swings of mood and anger and responded quickly to suggestion. Her ambitions were out of keeping with her possibilities as she wished to be a doctor, a nurse or a beauty operator. She refused to admit that her facial deformity as well as her educational limitations would keep her from these occupations. She had met her difficulties by hiding behind her facial disfigurement which she used as

a rationalization of her inability to make a social adjustment. We felt that with an intelligent and sympathetic program and facial reconstruction a fairly good result could be obtained.

A logical question arises at this point. Do all these persons with inadequate personalities fall into a psychopathologic state and become problems after the surgical experience? We think that "no" is the answer. There is the retiring, passive, apologetic person who finds his psychic adjustment through humility and forbearance and is everlastingly thankful for any interest or aid given or offered by his environment. He does not cause the surgeon trouble even if the surgical results are unsatisfactory.

The third group is composed of those persons who have a primary, or basic, personality inadequacy. They are unable to assimilate and digest the demands and restrictions of their environment or to measure up to their opportunities and in casting about for a plausible basis for rationalization come, by chance perhaps, on a minor defect, such as a mole, acne scar, freckles, a long lip or an unequal nostril. From this they build an all-inclusive rationalization of their difficulties, out of all proportion to the reality values of the deformity. Furthermore, there are conscious and unconscious meanings to those deformities or defects.

Any plastic or reconstruction procedure only serves to interrupt the rationalization process, and soon the resulting scar or some other trivial defect is seized on for continuation of the delusional and illusional construction, which is often frankly schizoid.

When such patients appear for surgical aid one is wise to proceed with greatest caution, and it is suggested that physiologic function alone be used as the criterion for operative intervention. This criterion is offered because the emotional importance of the disfigurement is secondary to a basic prepsychotic personality and regardless of the technical success the procedure will serve only to diversify instead of to remove the expression of an incipient psychosis. Case 11 is a classic example of this group.

A youth had a small white scar on his forehead which was undetectable without close observation. He was tall, slender and asthenic, with many facial mannerisms, was reticent and emotionally unstable and seemed perplexed at times. He felt that this small scar was responsible for his inability to make a satisfactory social and occupational adjustment, and it had been the reason for his seclusiveness for the past two years. His mother, who was tuberculous, died when he was 10, after many years of strife with an alcoholic father, who deserted the children soon after her death. He was raised in a tuberculosis hospital and an orphanage and by foster parents. In the second year of high school he became seclusive and disinterested in social activities, his lessons became difficult and he had some change in personality, which he attributed to a small mole, which was removed by electrolysis. After about one year he transferred his rationalization from the mole to the resulting scar, where it remained to this time. He had joined the navy about two years before and was dissatisfied with his advancement. He was prone to blame the aforementioned scar for his difficulty in adjustment and was unable to accept any other explanation despite logic or reason. It is obvious that he was definitely in the early stages of schizophrenia and that operative procedure would only serve to precipitate a more active phase of his psychosis. No improvement of the basic condition could be attained by treatment of the presenting symptoms.

It is here logical to consider whether all the prepsychotic reactions are of the schizophrenic type. Other reactions were conspicuous by their absence in this study, perhaps they may be found later. The schizophrenic reaction is definitely the common and characteristic one.

In the cases available, the extroverted, affective personality types were absent, and practically all the members of the well adjusted group could be classed as outgoing types. This fact leads one to feel that either the extroverted, affective person adjusts to his facial deformities without surgical aid or that when he has an operation he offers the most adequate subject for aid from an emotional standpoint.

No attempt is made at this time to discuss the underlying psychobiology of the reactions observed, as prolonged study and contact are necessary for an understanding of them. This we hope to report in future communications.

It is our hope that the direction of attention to this fertile field will be productive of more satisfactory results for all concerned in this growing branch of surgery. The proper selection and preparation of the patient may at times be as helpful as the proper surgical technique and skill.

The question arises regarding how these types can be recognized by a busy surgeon. Experience must be the guide. In general, however, one must look at the patient as an integrated organism, in which the personality needs study as well as the somatic factors involved. We list herewith certain questions that might be kept in mind: 1. What was the personality prior to the disfigurement? 2. What was the patient's emotional status when he was first conscious of his disfigurement? 3. What part has the disfigurement played in formation of the present personality? 4. What will probably be the emotional effect of plastic removal of the facial defect?

These questions require only a general working concept of basic personality factors and mental mechanisms plus the judgment and common sense of the investigator. The cardinal requirement is an interest in the patient's makeup and from one to three hours of time, depending on the physician's ability and the patient's complexity. In this period if the patient is encouraged to talk of factors other than his illness, the aforementioned personality outline is used only as a guide (not as a rigid questionnaire) and the physician considers the effect, judgment, security, and relative value in the patient's productions as well as their superficial content, as a rule an excellent estimation can be gained in a relatively short time.

If time or circumstance renders it impossible to make the necessary effort, an opinion of a psychiatrically trained consultant will not be amiss and will usually be welcomed by the patient. Such a consultation will often forestall an unpleasant, prolonged and thankless effort on the part of the surgeon.

#### SUMMARY

A consideration of the personality and emotional status of the patient seeking a facial operation is recommended in an attempt to diminish the number of emotional defects which hound the surgeon after good technical results have been obtained. This can be achieved by a better understanding of mental and personal mechanisms on the part of the plastic surgeon and can be further facilitated by a closer association of the plastic surgeon and the psychiatrist. An estimation of the personality by one trained in that field as well as in the field of general medicine is recommended at least until the surgeon has acquired an insight and a workable concept of what personality factors influence the total result from the patient's standpoint.

## WHOOPIING COUGH

## NEW PHASES OF THE WORK ON IMMUNIZATION AND PROPHYLAXIS

L W SAUER, MD

EVANSTON, ILL

The coccobacillus of Bordet and Gengou (*Haemophilus pertussis*) has now been accepted quite universally as the sole causative factor of whooping cough, a filtrable virus plays no role. This pathogen, first isolated with difficulty from the coughed up, glistening pearls of mucus, can now be recovered with relative ease on cough plates exposed during the catarrhal stage. With the proper technique it has been recovered post mortem from alveoli and bronchi. It is not found in any other respiratory disease, intimately exposed immune subjects rarely harbor it.

## EXPERIMENTAL WHOOPIING COUGH

Various groups of investigators have produced clinical whooping cough in young monkeys (ringtails, rhesus chimpanzees) by nasal or intratracheal inoculation of recently isolated cultures. Furthermore, the paroxysmal cough, lymphocytosis and pathologic lesions were produced in monkeys inoculated with bacilli recovered from the finer bronchi of experimentally infected monkeys. To exclude any virus factor, Shibley<sup>1</sup> inoculated chimpanzees with a culture of *H. pertussis* that had been transplanted on suitable culture medium more than sixty times. Clinical whooping cough developed in the animals. In chick embryos inoculated with recently isolated cultures by Gallavan and Goodpasture,<sup>2</sup> pulmonary lesions developed microscopically similar to those found in human infection with whooping cough.

The human transmission experiment by the MacDonalds<sup>3</sup> brings strong evidence that a filtrable virus plays no etiologic role. Their four sons—two of them twins—aged 6, 8 and 9 years, all in good health, had not had whooping cough. Two of them had been vaccinated five months previously with a total dosage of 8 cc of *H. pertussis* vaccine (1 cc = 10,000 million organisms). The Chamberland L<sub>3</sub> candle filtrate of a recently isolated culture (half of the growth of the well seeded Petri dish, suspended in physiologic solution of sodium chloride, maintained at 37°C) was instilled into the nose and throat of each of the four boys. Symptoms did not develop in any of the boys in eighteen days. A colony from the intact half of the refrigerated plate was suspended in physiologic solution of sodium chloride. Approximately 140 bacilli were instilled into the nose and throat of each. The two vaccinated volunteers remained free from symptoms. Their cough plates were repeatedly negative and their blood counts remained normal. The two boys who had received no vaccine began to cough in a week, in the course of several weeks they showed all the clinical signs and symptoms of whooping cough. Their cough plates were repeatedly positive (+++), the blood counts rose to 29,200 and 29,100 respectively, lymphocytosis was marked. The paroxysms and vomiting persisted for weeks. Complement fixations on the four boys were four plus posi-

tive. The vaccinated boys remained well, although in the closest contact with the patients throughout the course of the disease.

The diagnosis of whooping cough without adequate proof is often misleading. Typical whooping cough in a sibling, intimate contact with a child in the catarrhal stage, a typical paroxysm or whoop, a positive cough plate early in the disease, typical lymphocytosis or a positive complement fixation test later substantiates the diagnosis. The typical whoop may be absent in infants and adults. Persons who had the disease months or years previously may again cough in paroxysms, whoop and vomit during subsequent respiratory infections without expelling the bacillus. Occasionally the disease is contracted by children a second time, more frequently by intimately exposed adult attendants, especially mothers and grandmothers. Without adequate tests it may be difficult to differentiate atypical whooping cough from other coughs. A protracted, paroxysmal contagious cough (without lymphocytosis or whoop) due to catarrhal tracheobronchitis may simulate clinical whooping cough. The paroxysmal cough of distemper (snuffle infection) in young children (contracted from pet rabbits, puppies, cats or infected children) can be differentiated from whooping cough by early cough plates or subsequent complement fixation and agglutination tests.

While using the cough plate in the diagnosis of whooping cough, Eldering and Kendrick<sup>4</sup> repeatedly isolated from children with paroxysmal coughs a new bacillus (*B. parapertussis*) which resembled *H. pertussis* in some respects, was like *B. bronchisepticus* in other respects but had some characteristics common to neither. The colonies resembled those of *H. pertussis* so closely that the children were quarantined as whooping cough patients. Only on subculture and further study were the differences found. It is not yet known whether children vaccinated with potent whooping cough vaccine would be protected against infection with this bacillus.<sup>5</sup>

Bradford and Slavin<sup>6</sup> reported the isolation of ten atypical strains, by the cough plate method, from children with pertussis-like coughs. Eight had been regarded as *H. pertussis* until further study showed clearly that they constituted an atypical group. The atypical strain was isolated from two infants in a contagious disease hospital, they presented all the clinical features of moderately severe whooping cough. The white blood cell counts were 17,500 and 36,600 respectively. Six of the strains were isolated from patients with what seemed to be "typical" cases of whooping cough treated at home. At that time there was a decided increase in the incidence of whooping cough in the city (Rochester, N. Y.). Eight atypical strains were isolated in a series of 160 consecutive "positive" cough plates—about 5 per cent of the "positive" plates. The atypical strains darkened the medium and showed early pleomorphism. They too resembled *B. bronchisepticus* in some respects but not in others. Each atypical strain was strongly antigenic when injected into rabbits. They suggest that all whooping cough vaccine for immunization should include an atypical strain. (This would weaken the vaccine and would probably not be strong enough to protect against atypical strains.)

VACCINATION AGAINST WHOOPING COUGH

The efficacy of an antigen is usually interpreted in two ways (a) by serologic tests—complement fixation and agglutination (antibody responses similar to those produced by the disease), (b) by the severity of the disease, if infection occurs. Because both possess sources of error, views on the efficacy of vaccine differ. Complement fixation and agglutination tests do not actually prove the presence of immunity, without the injection of any antigen an appreciable number (more than 20 per cent, according to some epidemiologists) of exposed children who have not had whooping cough do not contract it when exposed, those who contract it show wide natural variations in severity.

The ultimate test of vaccine-conferred immunity is a comparison of results in similar groups of intimately exposed unvaccinated (control) and vaccinated susceptible persons in the same age range—preferably between 8 months and 3 years—the age period when the incidence of the disease is highest.

MUNICIPAL CONTROL OF WHOOPING COUGH

At the Evanston Health Department Whooping Cough Control Clinic conducted semiannually since 1934,<sup>8</sup> a total of 1,377 infants and young children (average age about 9 months) have been vaccinated. To date, a total of ten of the vaccinated children con-

quired, the three weekly injections are given just under the skin in alternate arms. The total dosage for children under 2 years of age is 5 cc (1, 2 and 2 cc at weekly intervals). The total dosage for children over 2 years is 6 cc (1, 2 and 3 cc at weekly intervals). If desired, the injections may be given at intervals of two or three weeks. The first two injections are given in the deltoid regions, the third is given in the left triceps region.

FAILURE OF ANTIGEN TO CONFER PROTECTION

An antigen fails to elicit specific antibodies in sufficient amount for prolonged immunity if it does not contain a sufficient concentration of the essential immunizing substance, if the injected dosage is inadequate or if the time interval between injection and exposure is not sufficiently long. Children over 2 years of age require a somewhat larger total dosage. Failure may result from impotent vaccine (old cultures, denaturing effect of preservatives, inadequate refrigeration), insufficient dosage for age, error in administration (deep injection in place of just under the skin), inability to develop antibodies from the injected antigen (premature exposure, too young) or premature loss of immunity (improper spacing, intercurrent diseases).

REACTIONS<sup>9</sup>

Parents are forewarned that a transient local reaction (redness and tenderness) and a rise in temperature may follow an injection. Reactions usually subside within thirty-six hours. A local induration or subcutaneous nodule may persist for a week or more. Nothing should be applied locally. Injections are not given in the area of a previous diphtheria toxoid injection or smallpox vaccination.

COMPLEMENT FIXATION AND AGGLUTINATION TESTS

Complement fixation and agglutination tests, performed with recently isolated cultures, maintained on a suitable culture medium, are usually positive with serums collected after the height of the disease or after adequate vaccination with potent vaccine. Gundel, Keller and Schluter<sup>10</sup> found that the complement fixation test remains negative in a very small proportion of patients with whooping cough—mostly infants who failed to produce antibodies and in whom the disease was often fatal. They found the antibody response after vaccination better when freshly isolated cultures rather than old laboratory strains were used. They proved the futility of the injection of vaccine during the paroxysmal stage.

Since 1934, Daughtry-Denmark<sup>11</sup> has used the test as a routine a month or more after the third injection of authorized vaccine. If fixation was not complete (four plus), an additional 3 cc of authorized (or 1.5 cc of "double strength") vaccine was given. Later on, if the retest did not show complete fixation, a final 3 cc (or 1.5 cc "double strength") vaccine was given. The Webb<sup>12</sup> modification of the complement fixation technic

Controlled Vaccinations with Authorized Haemophilus Pertussis Vaccine \* (Jan 1, 1933, to Oct 1, 1936), Age Range 6 Months to 4 Years

Groups		Number	Contracted Whooping Cough
Private, from 1933	Unvaccinated (controls)	540	10
	Vaccinated	1,001	16
Evanston Department of Health from 1934	Unvaccinated (controls)	1,100	129
	Vaccinated	1,377	10
St. Vincent's (1935 epidemic)	Unvaccinated (controls)	70	52
	Vaccinated	70	6
Totals	Unvaccinated (controls)	1,730	286
	Vaccinated	2,453	2

\* Since March 1 1938 only double strength vaccine (1 cc = 20,000 million organisms) has been used total dosage from 80,000 to 100,000 million.

tracted whooping cough more than three months after injection. For the decade ending in 1933 the average yearly city total of reported cases of whooping cough was 334. In 1936 the city total was ninety-one, the lowest yearly total in the history of the department of health. In one clinic child the disease developed shortly after vaccination, none of the remaining ninety patients in the city had received vaccine. In 1937 the city total was 131 cases, chiefly among the Negro children, whose parents had remained rather reluctant about whooping cough vaccination. Of twenty-seven vaccinated Negro children subsequently exposed to whooping cough in their unvaccinated siblings, mild pertussis developed in three whereas in twenty-four the disease did not develop.

Since March 1938 both laboratories licensed by Northwestern University Medical School to make authorized H. pertussis vaccine for immunization have supplied us with so-called double strength vaccine (1 cc = 20,000 million organisms). It will be available in the near future. Owing to the smaller volume

7 This difference of opinion on the immunizing virtue of vaccine is augmented by the various ways in which vaccines have been made—from old stock strains or recently isolated cultures some mediums contain blood others do not some vaccines are washed others are not washed.

8 Sauer L. W. Inoculations Against Whooping Cough J. A. M. A. 109: 487 (Aug. 14) 1937.

9 When the heat sterilized syringe is reused without resterilization as is customary more than one child is injected the used needle should be cautiously replaced with a sterile one without the tip of the syringe being touched. To avoid contamination of vaccine with resultant local infection only the very end of the plunger should be touched as the syringe is being filled and discharged.

can be performed in any laboratory equipped to make Wassermann tests. At the Atlanta Whooping Cough Control Clinic a total of 600 children were tested after vaccination. Twenty-eight were subsequently directly exposed to whooping cough, none contracted it. During the same five years, 174 of 192 nonvaccinated (control) children of the same social group contracted whooping cough. If a complement fixation test is not performed, Daughtry-Denmark recommends a total of 7 cc of "double strength" vaccine. She concludes "If complement fixation is indicative of antibody response, a four-plus fixation test has definite significance."

Miller found that washing *H. pertussis* (phase I) vaccine with distilled water or with 0.85 per cent solution of sodium chloride removed a specific substance which could be flocculated by hyperimmune rabbit serum. He concluded that this constitutes grounds for the omission of washing in the preparation of vaccine.

#### TESTS FOR VACCINE POTENCY

Burnet and Timmins<sup>13</sup> produced a fatal pulmonary infection in anesthetized mice by nasal inoculation of living *H. pertussis*, mice previously vaccinated with potent vaccine withstood the lethal dose. They suggest the use of this test in the evaluation of vaccine used in immunization.

Powell and Jameson<sup>14</sup> found that mice injected with three weekly doses of 0.1 cc of authorized vaccine withstood, one month later, the lethal dose of starch-treated living bacilli. They were the first to establish quantitative differences in the immunizing effectiveness of pertussis antigen. Silverthorne and Frazer, and Silverthorne<sup>14a</sup> injected mice with the authorized pertussis vaccines, other fresh strain vaccine, stock strain vaccines and "antigens." Only mice vaccinated with the authorized and other fresh strain vaccines withstood subsequent intraperitoneal injections of lethal doses of mucin-treated living cultures. They suggested that vaccine for immunization should be so tested before release.

Park and Mishulow,<sup>15</sup> Shorr<sup>16</sup> and Blatt, Levin and Schapiro<sup>17</sup> gave whooping cough vaccine intradermally. Park and Mishulow believe that a better response occurs with a smaller volume of vaccine. Shorr abandoned the intracutaneous technique because "of the marked local reactions and the large number of injections necessary to give a total anywhere approaching the proposed dosage. The largest single injection given intracutaneously was 0.2 cc and the total amount did not exceed 1 cc in any child."

#### CUTANEOUS TEST

Gundel, Keller and Schluter tested dilutions of *H. pertussis* endotoxin as a cutaneous test. It showed no specificity, nor was its necrotizing action neutralized by the addition of convalescent serum. Mishulow, Mowry and Scott obtained a toxic filtrate by growing the bacillus on horse blood-chocolate agar with 1 per cent horse serum-beef heart broth. The Shwartzman phenomenon was produced with the filtrate. Koplik neutralized the toxin with convalescent serum. Truschina,

Pechlotzkaja and Murawjowa<sup>18</sup> prepared a toxin which seemed to possess immunizing properties. Addition of 0.2 per cent solution of formaldehyde rendered it less toxic, when injected into animals, the toxin produced antibodies. Intradermal injection of diluted toxin in nonimmune children produced lesions resembling the Dick test. Their work has not yet been confirmed. Cruickshank and Freeman<sup>19</sup> isolated an antigenically active fraction from phase I bacilli. Tested in mice, it appeared to possess an immunizing potency equal to that of phase I vaccine. Miss Leonora Hambrecht and I produced whooping cough bacteriophage by growing young cultures of old strains in a concentrated fresh sewage bouillon filtrate which contained a small amount of defibrinated human blood. Lysis was transmitted in series, and platings made from such lysed tubes produced typical plaques.

Thompson<sup>20</sup> reviewed the work of others on a cutaneous test for whooping cough and tabulated his own observations on immune and nonimmune subjects with 0.1 cc of authorized vaccine (undiluted and diluted 1:10) and an endotoxin (diluted 1:5 and 1:10). Bacterial hypersensitiveness (positive cutaneous test) appeared about the tenth day of illness, reached a peak during the course of the disease and then usually receded. In some it did not completely disappear. The test seemed to be valuable in determining the immune state of a person, also as a diagnostic aid in atypical or missed cases when the cough plate was negative. He did not determine whether the positive cutaneous reaction indicated sensitization or immunity.<sup>21</sup>

#### PROPHYLAXIS

Bordet discontinued the use of whooping cough antitoxin as a prophylactic or curative agent because its questionable value did not warrant the hazards of anaphylactic reactions, serum sickness and sensitization to horse serum. Although the organic damage caused by endotoxin produced by the invading bacilli during the disease is not counteracted by whooping cough antitoxin, Schluter recently reported on the early use of a concentrated, more potent antitoxin prepared by the injection of larger doses of toxic cultures. Toomey reported that the injection of whooping cough antiserum aggravated clinical symptoms.

#### CONVALESCENT SERUM

Degkwitz was probably the first to report favorable results with convalescent serum in infants and young children when injected in the incubation and early catarrhal stage. Bradford<sup>22</sup> recently reviewed the literature on convalescent serum and whole blood in whooping cough. He recommended 10 cc of human convalescent serum or 20 cc of immune adult blood before catarrhal symptoms appear. Meader<sup>23</sup> recom-

18 Truschina N, Pechlotzkaja W and Murawjowa O. *Ztschr f Immunitätsforsch* 83: 124 (1934). Cutaneous tests with their toxin kindly sent to us failed to differentiate immune from nonimmune children. Deterioration while in transit is probably the cause of our negative results.

21 Dilution of authorized vaccine also of the clear supernatant liquid after prolonged centrifugation often gave cutaneous reactions like those described by Thompson. When 0.1 cc of authorized vaccine or its clear supernatant liquid after prolonged centrifugation diluted (1:8) with 0.5 per cent phenol in 0.85 per cent saline solution was injected intracutaneously into the skin of the forearm after whooping cough or several months after completion of vaccination against whooping cough, a local reaction that measured more than 10 mm in diameter was frequently observed twenty-four hours later. Nonimmune persons usually showed a smaller or negative reaction.

mended the prompt injection of from 10 to 15 cc of pooled convalescent serum within the first week after exposure. In 72 per cent of the exposed infants so treated whooping cough did not develop, whereas in 30 per cent of the exposed but not injected (control) infants in the same age group the disease did not develop. Bessau observed no advantage in convalescent serum even when large amounts were injected early. Bordet holds that young infants are less susceptible to whooping cough because many possess, for the first few months, antibodies transmitted through the placenta from the immune mother.

Jundell injected parents preferably those who had had whooping cough in childhood, with three doses of vaccine at intervals of three days. He reported good results with such 'hyperimmune' convalescent serum when given in the incubation or early catarrhal stage. Because valuable time was lost by waiting, Kendrick<sup>24</sup> prepared hyperimmune serum by the injection of the Michigan whooping cough vaccine into donors. Such hyperimmune serum was injected into infants soon after exposure with apparent benefit.

#### LYOPHILE SERUM

McGuinness, Stokes and Mudd<sup>25</sup> pointed out that improved technical procedures for preservation, pooling and concentration of human serum facilitated the use of serum in the passive immunization of exposed infants. Pooled serums are preserved by drying in vacuo. The dry, yellow, porous material ('lyophile' serum) was redissolved in sterile distilled water just before use. It was usually injected in doubly concentrated form.

Twelve infants between 1 and 7 months of age, exposed for two weeks in a ward to an early case of whooping cough with a fatal outcome, were injected with lyophile serum on the twelfth day following the initial exposure. Eight received 10 cc and four received 20 cc. Whooping cough did not develop in any of the twelve. For two days a child of 10 years was exposed to a sister with whooping cough, 20 cc of the pooled adult serum was injected and whooping cough did not develop. Healthy adult donors who gave a history of whooping cough were injected with the routine course of authorized whooping cough vaccine, one full course of vaccine was given every four months. After four months the donors were repeatedly bled at varying intervals. Diluted lyophile whooping cough serum was injected into twelve children intimately and continuously exposed to siblings with whooping cough. Previous attacks of whooping cough could be definitely excluded. In six the disease did not develop, in three a cough developed which lasted for from ten days to two weeks but was not associated with a characteristic whoop, in the remaining three children typical but mild whooping cough developed. Fifteen patients with clinical whooping cough were treated. Five appeared improved and the other ten were not benefited. They concluded that lyophile serum was of prophylactic value for passive protection,<sup>26</sup> after the disease was active, its value was uncertain.

#### CONCLUSIONS

Whooping cough is caused by *Haemophilus pertussis* (coccobacillus of Bordet and Gengou), a filtrable virus plays no role

*Bacillus pirapertussis* (Eldering and Kendrick) causes a pertussis-like cough.

The newly recommended concentration of authorized *H. pertussis* vaccine (1 cc = 20,000 million organisms) requires a smaller volume of vaccine for active immunization.

It is not yet known whether the frequently observed positive cutaneous test (after the disease and after active immunization) is an allergic phenomenon or actual proof of immunity.

The present strongest laboratory evidence of vaccine conferred immunity is a four-plus complement fixation test.

Passive immunity, according to various investigators, occurs when intimately exposed infants are promptly injected with convalescent or hyperimmune serum before the paroxysmal stage.

## Clinical Notes, Suggestions and New Instruments

### KALA-AZAR

DON R. MATHIESON, M.D. AND B. A. WATSON, M.D. MINNEAPOLIS

This case of kala-azar is reported because of the infrequent occurrence of this disease in the United States.

C. Y., a Chinese student aged 29, entered the United States from China Sept. 3, 1935. Prior to that time he had been engaged as a teacher and research worker in parasitology and entomology. He came to this country for graduate study at the University of Minnesota. His general health had always been good with the exception of several attacks of malaria.

Fig. 1.—Smear showing Leishman-Donovan bodies

On admission to the Students' Health Service the patient stated that about Dec. 15, 1935, he began to notice increased fatigue on moderate exertion, loss of appetite and slight dizziness. These symptoms increased in severity until December 21, when he was confined to bed, where he remained until the date of admission, Jan. 7, 1936. During this interval "chills" sensations and fever, nosebleeds, bleeding gums and loss of hair were noted.

From the Medical Service of the Students' Health Service, University of Minnesota.  
Dr. Watson is physician, Students' Health Service, and assistant professor of preventive medicine, University of Minnesota Medical School.

<sup>24</sup> Kendrick, Pearl. *J. Pediat.* 9: 117 (July) 1936.  
<sup>25</sup> McGuinness, A. C., Stokes, Joseph Jr. and Mudd, Stuart. *J. Clin. Investigation* 16: 185 (March) 1937.  
<sup>26</sup> Since the benefit of passive immunization is temporary, children so injected should also be given the three customary injections of authorized vaccine for prolonged protection.

On physical examination at the time of admission it was noted that the patient was fairly well developed but slightly emaciated. He appeared weak and fatigued but not acutely ill. The temperature was 100.6 F, the pulse rate 100 and the respiratory rate 20. The hair was dull and dry. The skin was clear. The eyes, ears, nose and throat were normal. The breath was foul. The tongue was clean and moist. The gums of the maxilla were bluish purple. There was dried and caked blood on the alveolar margins of the upper incisor teeth. There was no cervical adenopathy. The thyroid was not palpable. The lung fields were clear. No rales or other abnormal sounds were made out. The heart appeared to be normal in size, shape and position. A soft systolic murmur was heard in the second left interspace. The blood pressure was 110 systolic, 54 diastolic. The abdomen was protuberant. The spleen was enlarged extending below the umbilicus. It was firm and had a smooth edge. The liver was enlarged and palpable to about 3 cm below the costal margin to the right of the midclavicular line. Neurologic examination gave negative results. The white blood cell count was 2,700, the red blood cell count 3,000,000 and the hemoglobin content 60 Sahli units. The differential blood count showed 60 per cent polymorphonuclears and 40 per cent lymphocytes. Culture of material from the nose and throat was negative.

An admission diagnosis was not made. The patient remained for observation and further study. A Mantoux test (1:100 dilution) was negative. A roentgenogram of the chest showed nothing abnormal. Because of the patient's history of recurrent attacks of malaria and the splenomegaly, numerous blood

Fig 2—Response of the temperature to treatment

smears were made and examined for malarial parasites. Though none were found, a course of quinine was administered definitely to rule out malaria. A total of 75 grains (4.8 Gm) was given over a three day period. With the onset of toxic symptoms administration of the drug was discontinued. It had in no way altered the course of the illness. Because the patient had been doing experimental work with pathogenic filaria worms a night specimen of blood was obtained and examined for filaria worms. None were found. Agglutination tests with the patient's serum and antigens of tularemia and undulant fever were negative. The possibility of kala azar was suggested. A formal-gel test<sup>1</sup> was carried out. The result was strongly positive. Test of a control serum gave negative results. The patient had become weak and listless. Afternoon temperatures were becoming higher. Marked anemia (29 Sahli units of hemoglobin) had developed, and marked leukopenia, with a count of 1,800, was present. At this time (fifteen days after admission) a splenic puncture<sup>2</sup> was done. Smears were made which showed the presence of Leishman Donovan bodies (fig 1). Cultures were made on N N N medium. The patient at this stage was acutely ill and hope for recovery was slight.

A course of treatment with antimony was immediately started. This consisted of intramuscular injections of fuadin<sup>3</sup> on alternate days. The patient was given a transfusion of 300 cc of citrated blood every other day. After six days treatment his

condition became critical. His temperature was 105 F, his pulse rate 134 and his respiratory rate 28. There were petechiae over the abdomen, in the axilla, in the folds of the elbow, and on the right leg. There was also at this time a considerable accumulation of fluid in the peritoneal cavity. The platelet count was 20,430 per cubic millimeter. Up to this time a total of 125 mg of trivalent antimony compound had been given. The day following the last injection the temperature dramatically dropped to normal and the patient's general appearance was surprisingly improved. After two days' interval treatment was resumed, with the use of stibamine glucoside (neostam)<sup>4</sup> in place of fuadin. A total of 2.06 Gm was given in forty-three days. The only toxic manifestations noted were slight headache, urticaria and dry, nonproductive cough at the time of injection. These were well controlled by codeine and epinephrine. Figure 2 shows the response of the patient's temperature to various types of therapy.

At the time of discharge from the hospital the patient had made an apparently complete recovery. His blood picture was normal. The spleen had decreased in size and the liver was no longer palpable. The patient was able to resume his studies and in August 1937 was granted a Ph D degree in parasitology.

#### THE PROTHROMBIN TIME OF BANK BLOOD

JONATHAN E. RHOADS, M.D. AND LILLIAN M. PANZER  
PHILADELPHIA

The institution of "blood banks" in many of the larger hospitals throughout the country has often made the clinician entirely dependent on stored blood for transfusion. That such blood is not equivalent to freshly drawn blood in all respects is becoming increasingly apparent.

For several years it has been a routine procedure at the Hospital of the University of Pennsylvania, in the service of Dr. I. S. Ravdin, to transfuse jaundiced patients in the surgical wards both before and after operation and to combat any manifest hemorrhagic tendency with repeated transfusions. The work of Quick,<sup>1</sup> as well as that of Brinkhous, Smith and Warner<sup>2</sup> and that of Dam and Glavind,<sup>3</sup> has provided a rational basis for the belief that transfusion may diminish the hemorrhagic tendency in jaundice. They have shown that the hemorrhagic tendency of jaundice is associated with a prothrombin deficiency and that normal blood contains a great excess of prothrombin beyond the amount necessary for clotting. Because of this work it seemed important to determine the prothrombin content of blood stored in the blood bank, of the Hospital of the University of Pennsylvania at various intervals.

A modification of Quick's method<sup>4</sup> was employed. The technique recommended for taking samples could not be followed because the blood in question had already been citrated.

Two cubic centimeters of each flask of blood was transferred to a sterile test tube the morning after it was drawn. Half of this amount was removed, the plasma was separated by centrifugation and immediately tested for prothrombin time. The other half remained in the blood bank with the flask from which it was taken. The temperature was regulated to 4 C. In forty-two instances this sample was tested on the third day, in sixty-six instances on the seventh day and in twenty-six instances on the tenth day. The average prolongation of the prothrombin time was computed in percentage and the results are shown in the accompanying chart.

Using serial dilutions with plasma in which the prothrombin has been inactivated with aluminum hydroxide as described by Quick,<sup>4</sup> we have found that a 40 per cent prolongation in

3. Sodium antimony III bisacatechol-disulfonate of sodium.

prothrombin time indicates a decline to about 20 per cent of the original prothrombin concentration and that a 35 per cent prolongation in the time corresponds to a concentration of less than 25 per cent of the original prothrombin. The 17 per cent prolongation falls in a part of the curve in which small differences in the time represent large differences in the prothrombin concentration and represents a loss of over half of the prothrombin.

We conclude, on the basis of the Quick method, that blood that has been in the bank a week or more would be practically

#### *Prolongation of Prothrombin Time*

Average percentage increase in prothrombin time in specimens of bank blood

useless in the treatment of the acute prothrombin deficiency encountered in jaundiced patients not adequately treated with vitamin K and bile salts. Blood that has been in the bank three days would probably be of some slight value but it would be so inferior to freshly drawn blood that we recommend that only the latter be used when the transfusion is intended to combat the hemorrhagic tendency in jaundice.

#### METRAZOL THERAPY IN SCHIZOPHRENIA

REPORT OF A FATAL CASE WITH AUTOPSY

MAX HAYMAN, M.D., AND MORRIS W. BRODY, M.D.  
SILFESSVILLE, MD.

There has been much enthusiasm recently for metrazol therapy of the functional psychoses. This is based on the dramatic remissions, on its ease of administration and on its adaptability to the treatment of large groups of patients. The literature, however, is still too meager to acquaint one with all the potential dangers attendant on the treatment. Meduna has treated more than 400 patients without a single death, in all, upward of 1,500 patients must have received metrazol therapy.<sup>1</sup> Severe headache, nausea and vomiting, fractures and dislocations, and many minor complications are common, but to date only three fatal cases have been reported. We record in detail, with autopsy, a case under metrazol therapy which terminated fatally.

#### REPORT OF CASE

**History**—D. G., a white man aged 24, since June 1936 had complained of nervousness, weakness, trembling, pains in the head, back and abdomen and a subjective sensation of high blood pressure. The latter symptom was associated with a feeling of hot fluid running up his spine. Following two previous periods of hospitalization he was committed to the Springfield State Hospital, Dec. 8, 1937. Here he was seclusive, preoccupied and retarded, he believed that people pursued him

and that voices cursed him and called him obscene names. He held fixed positions and was often mute. Other than measles and mumps and a tonsillectomy in childhood he had had no significant illnesses. One sister died of "meningitis of the brain" at the age of 8, but otherwise the family history was noncontributory.

**Examination**—**Physical Status**. The patient was tall and of athletic build. The heart showed no clinical enlargement, rhythm was regular and there were no adventitious sounds. The blood pressure was 120 systolic, 84 diastolic. The lungs were normal. Neurologic and eye-ground examinations were negative. Other than poor dental hygiene and a relaxed right inguinal ring, no physical abnormalities were noted.

**Laboratory Studies**. On admission the red blood cell count was 4,220,000, hemoglobin content 86 per cent and white blood cell count 8,200 with a normal differential. Repeated urinalyses were negative. Blood chemistry, including dextrose, nonprotein nitrogen and uric acid, was within normal limits. Examination of the spinal fluid was negative as were Wassermann reactions of the blood and spinal fluid. These studies and physical examinations repeated immediately before institution of metrazol therapy, showed no essential change.

The clinical diagnosis was schizophrenia of the catatonic type.

**Treatment**—Metrazol therapy was instituted Feb. 22, 1938. Three cc. of a 10 per cent solution of metrazol was given intravenously. Thirty seconds after the injection the patient gasped and there were blinking of the eyelids, dilatation of the pupils, flushing of the face and an increase in the pulse rate. Other than a few irregular movements no convulsion occurred. The following day he was preoccupied and retarded, there was some twitching of the facial muscles and he spoke of the treatment being "blurry, like electricity."

February 26, 4 cc. of metrazol was given. The patient became tense but showed no other reaction. Again he had the sensation of electricity and was slightly nauseated in the afternoon.

March 1, 5 cc. of metrazol was given. Ten seconds after the injection there was a sudden contraction of the body with the legs and shoulders raised stiffly from the bed. Without preliminary clonic movements an immediate tonic spasm set in which was followed by clonic movements becoming progressively slower and of greater amplitude. Immediately after the convulsion the patient became restless and appeared fearful of the examiner. He showed flexibilitas cerea for five minutes after the convulsion. In ten minutes he recognized the physician.

March 5, with 5 cc. of metrazol the patient reacted with the usual clonic-tonic-clonic metrazol convulsion. Again he seemed anxious and frightened afterward. The following day he complained of headache and nausea which persisted at intervals for three days; treatment was omitted March 8.

March 15, with 5 cc. of metrazol the patient reacted again with the usual convulsion, with a prolonged tonic and terminal clonic phase. A short series of clonic movements occurred a few seconds after the cessation of the convulsive seizure. The pupils were fixed and dilated, and there was conjugate deviation of the eyes to the left. He again showed flexibilitas cerea. In fifteen minutes he was able to respond and expressed hallucinations.

March 19, 5 cc. of metrazol was given. An atypical convulsion followed. Immediately after the injection a few irregular clonic convulsive movements occurred, most marked on the right side. Intense motor activity was present for a very short while and the patient tossed about on the bed. The pupils were dilated and remained fixed. The face, showing alternate pallor and flushing finally remained pallid. The irregular convulsive movements were present for two minutes and became rapidly weaker and finally the body relaxed. The pulse became weaker, was imperceptible at the wrist, and finally heart sounds became inaudible. Irregular respirations ceased. There was no cyanosis. Caffeine with sodium benzoate was administered intravenously, and artificial respiration was immediately instituted. Within three minutes 1 cc. of epinephrine was injected intracardially but heart sounds did not reappear, the patient could not be revived.

**Pathologic Examination**—Autopsy was performed five hours after death. All the organs of the body were intensely congested. The heart weighed 315 Gm., it was large and flabby.

<sup>1</sup> Cook, L. C. Cardiazol Convulsion Therapy in Schizophrenia. *Proc. Roy. Soc. Med.* 31:4 (April) 1938.

and filled with large quantities of blood. There were numerous, slightly raised fibrous nodules scattered through each of the cusps of the mitral valve, which was moderately thickened but not fixed. There was very slight ventricular hypertrophy. The brain was enlarged, edematous and remarkably congested but showed no other gross abnormalities.

The nodules in the mitral valve consisted of fibrous tissue with hyalinization and some scattered deposits of calcium. Similar scarring and deposits extended inward into and about the muscle bundles, replacing small areas of the latter with fibrous tissue. Small deposits of cholesterol were evident in parts of the valve. None of the other valves were involved.

The pleurae evidenced markedly congested blood vessels, as did the medium sized and small blood vessels of the lungs. The alveolar capillaries, however, were devoid of blood. Many small sections of the lung showed collapsed alveoli; other sections showed edema or extravasation of red blood cells into the alveoli.

The sinuses of the spleen were enormously distended with blood. The liver cells were swollen and the sinuses contained considerable blood. Here also the vessels were markedly congested. Moderate round cell infiltration was present in the periportal area, with lymphocytes, fibroblasts and occasional plasma cells. The kidneys and adrenals showed the same congestion but no other abnormalities.

The microscopic sections of the brain were prepared in the Neurological Laboratory of the Henry Phipps Psychiatric Clinic and the slides were studied by Dr Ellis Margolin. The leptomeninges showed no thickening and appeared normal. There was no distortion of the normal architecture of the brain. No gross or petechial hemorrhages were evident and there were no scars or areas of softening. The blood vessels showed no pathologic changes but were markedly congested with blood. The individual nerve cells showed no abnormalities.

The diagnosis was chronic endocarditis, pulmonary edema and acute cardiac dilatation. The probable cause of death was the toxic effect of a pharmacologic agent on a pathologically impaired heart.

#### COMMENT

On the sixth treatment with metrazol a man aged 24, whose physical and laboratory examinations were negative, suddenly died. The morbid anatomy showed marked congestion of all the organs and a pre-existent endocarditis. Except for the latter, the changes were essentially the same as those described by de Morsier and his associates<sup>2</sup> in their studies of a rabbit dying during a metrazol convulsion. No specific lesion was found at autopsy and the animal was apparently pushed beyond its physiologic limit of endurance.

The literature to date, as far as we can ascertain reports three deaths in association with metrazol therapy. In all three cases a pre-existing pathologic condition was present: aortic disease in one,<sup>3</sup> bilateral hypernephroma and goiter in the second, and pulmonary embolism and pelvic thrombophlebitis in the third.<sup>4</sup> In our own case a clinically asymptomatic and unsuspected chronic endocarditis was the underlying pathologic lesion. Other than the two fatalities presenting cardiac disease (Angyal and Gyrfas and our own), Goldstein and his associates<sup>5</sup> mention the occurrence of cardiovascular collapse in one of their patients. From our experience with metrazol in a case with a minimal heart lesion we feel that it is not as innocuous as is generally supposed. To keep the mortality rate at a minimum thorough physical examination and routine laboratory studies must be supplemented, as Low and his associates<sup>6</sup> suggest, by basal metabolic tests, x-ray examination of the chest and electrocardiograms.

### THE PROGNOSIS OF SYPHILIS

HUGH J MORGAN, M.D.

NASHVILLE, TENN.

In one of a series of lectures in therapeutics delivered in this country in 1933 Dr Francis Fraser<sup>1</sup> of Saint Bartholomew Hospital, London, said:

So long as there is no anxiety medical advice is not sought, and when fears arise they may not be expressed, and are often scarcely realized, but it is well that the physician should appreciate that fear is present and that it is no less real because it is not confessed. What the patient is really saying is "What does this symptom or this loss of efficiency mean to me, to my future?" and "Can you make me well?" The duty of the physician is then clear, he must endeavor to answer these questions, and the answer to the first is dependent on the answer to the second. The answer to the first question, or the prognosis, cannot be given unless the disease process present is known and the stage in the process that has already been reached, and the value of any curative treatment available must be weighed.

It is the purpose of this paper to bring together certain data concerning the prognosis of the disease syphilis in its natural, untreated state and to assess in the light of these data the value to the patient of modern treatment. My consideration of the problem then is restricted in the main to the disease from the point of view of the individual and not of the public health.

#### ASYMPTOMATIC INFECTION

Although one is accustomed to think that the establishment of syphilitic infection is heralded by the development of chancre at the site of inoculation, it is evident that this does not always occur. Indeed it seems probable that a considerable number of persons acquire syphilis without ever exhibiting signs or experiencing symptoms of the acute stage of the infection. What mechanism operates to bring about the suppression of visible reactivity to infection is entirely unknown. Certain facts, however, are of interest in this connection and may be of importance.

*The Inoculum*—The quantity of the inoculum may play a part. Asymptomatic infection may be induced in the rabbit by decreasing the amount of the inoculum to a point where demonstrable lesions do not occur. In 1934 it was demonstrated that in order to induce experimental infection more than a few organisms are required.<sup>2</sup> In recent unreported experiments Vryonis and I have been unable to produce lesions in rabbits with inoculums containing less than 30,000 spirochetes.<sup>3</sup> Nevertheless, under such circumstances infection can be proved to have become established. In the human disease there is evidence in the form of asymptomatic infection that an analogous state of affairs may exist.<sup>4</sup>

**Age**—Fournier<sup>5</sup> pointed out in 1899 that acquired syphilitic infection is prone to be more violent or florid in its manifestations in either prepubescent or elderly patients than in young adults or middle-aged persons. Although in agreement, I have no evidence to support this contention other than clinical impressions. Certainly congenital syphilitic infection in infants is commonly fatal,<sup>6</sup> and the incidence of asymptomatic congenital syphilis is much lower than that of asymptomatic

festations of acute syphilis, but apparently it also helps to protect the woman against the serious late sequelae of syphilitic infection.

The importance of detecting asymptomatic infection is great. Since its presence is not suggested by either clinical signs or symptoms, it tends to remain unrecognized, and indeed can be recognized only by serologic tests. Thus there exists in the population a large unrecognized reservoir of syphilis, potentially capable of spreading infection by the development of mucocutaneous lesions and in the case of women by the transmission of the infection to offspring. Furthermore, the threat of subsequent development of cardiovascular syphilis or neurosyphilis would seem to be great in asymptomatic syphilis. At least half of the patients who acquire these serious, often lethal, sequelae have had asymptomatic infection.<sup>8</sup>

Fig. 1—Possible course of syphilis

matic acquired syphilis. Moore<sup>7</sup> emphasized that the chief difference between the manifestations of early congenital syphilis and those of early acquired syphilis in the adult is quantitative and not qualitative. The visible manifestations in both instances are of the type designated secondary. The infant exhibits, besides, impressive clinical evidence of visceral involvement and toxemia. It seems probable then that the very young have not developed, and the very old may lose, the capacity to suppress acute manifestations of infection.

**Sex**—There seems little doubt that women experience asymptomatic infection quite frequently, indeed twice as frequently as men.<sup>8</sup> Certainly not more than one half of women with late syphilis can give a history at all suggestive of acute syphilis. This difference in the incidence or recognition of acute manifestations of syphilis in men and in women is also impressively reflected in clinic attendance. Men with acute syphilis greatly outnumber women. At the Vanderbilt University Hospital<sup>9</sup> 73.6 per cent of 497 patients with chancre were men and 26.4 per cent were women. Of 1,319 patients with mixed primary and secondary syphilis 62.4 per cent were men and 37.6 per cent women. This difference between the two sexes as to the clinical manifestations of acute syphilis is even more impressive when it is pointed out that among patients with latent and chronic, active syphilis females are slightly in the ascendancy in our clinic (53 per cent of 3,242 patients).

**Pregnancy**—Moore<sup>10</sup> has shown that the production of asymptomatic infection is favored by pregnancy. Not only does pregnancy tend to suppress the usual mani-

#### SYMPTOMATIC INFECTION

Figure 1 illustrates the course of symptomatic syphilis. After the virus has penetrated the skin or mucous membrane generalized infection rapidly develops. In rabbits it has been demonstrated that it requires only a few days for the organisms to traverse the barrier interposed by the lymphatic system and gain access to the blood stream.<sup>11</sup> Thus in animals it is established that generalized infection occurs before the chancre develops at the site of inoculation. This is known to be the case also in the human disease, since blood obtained from a transfusion donor in the prechancre (incubation) stage of syphilis has induced syphilis d'emblee in the transfusion recipient.<sup>12</sup> In acquired syphilis there is an interval of approximately three weeks before the local lesion develops at the site of inoculation and nine weeks before the mucocutaneous, ocular or meningeal manifestations of generalized infection become apparent. All these lesions represent tissue reactions to *Spirochaeta pallida*, which at this period in the disease is disseminated throughout the body. The chancre heals before, during or after the appear-

Fig. 2—Outcome of untreated acute syphilis

ance of the secondary lesions, and in the course of a few days, weeks or months there occurs spontaneous resolution of the latter. As healing occurs, dark field examinations of surface lesions indicate that widespread destruction of spirochetes is taking place. Massive generalized infection no longer exists. The disease thus becomes converted from a general infection to a focal one. Latent syphilis without signs or symptoms becomes established.

In this process the infected person has acquired the capacity for converting an active, generalized spirochetal infection with bacteremia into an inactive, focal infection, and this through the operation of factors of resistance native to the body. The mechanism of this immunity is not known. It develops during the stage of the early lesions of the skin and mucous membrane, and one is therefore inclined to emphasize the possible role played by these structures. This is known. While the immunity is effective and prevents death from an overwhelming spirochetal infection, such as occurs commonly in intra-uterine life, it cannot be proved to be totally effective in the sense of producing biologic cure. Spontaneous biologic cure of syphilis, with eradication of the last spirochete from the body, does not occur so far as is known. Nevertheless it would seem that the experience of a brisk reaction to acute infection with lesions of the skin and mucous membrane conveys a certain degree of protection against the late manifestations of the disease. It has been pointed out that the incidence of the late sequelae of syphilis is greater in persons whose histories indicate asymptomatic acute syphilis than in those who had as a result of the infection a chancre and rash. Moreover, the optimal time for treating seropositive acute syphilis, from the point of view of therapeutic results in individual patients, seems to be after the development and at least partial resolution of the frank secondary stage of the disease.<sup>13</sup> However this may be, in acute syphilis there is a limiting process which results in inactive infection, and this is brought about by natural immune forces. If these forces are potent, latency is permanent and reversals into the acute phase of the infection do not occur. If they are not potent, latency is not permanent and recurrences of the acute mucocutaneous lesions take place for months and even years. The highly infectious stage of the disease is thus prolonged.

Latent syphilis is an inactive, focal infection. The evolution of the disease now occurs in terms of years and decades, not of weeks or months, as in the acute period of the infection. The reactivity of the tissues of the body has become changed. When lesions develop they are no longer acute and actively inflammatory, as in the early phase of the infection, but are slowly proliferative and destructive. After a decade or more of symptomatic quiescence, progression of the disease from the latent state to active chronic infection may take place, manifestations of progressive changes in the vascular and central nervous systems begin to make their appearance, and the disabling, lethal phase of the infection appears. "Benign" lesions of skin and of bone may and often do occur, but the chief threat from the development of chronic inflammatory and degenerative tissue changes resides in the cardiovascular and central nervous systems. Equally grave, though much less commonly encountered, are the late syphilitic lesions of liver, rectum, lung and other organs.

#### PROGNOSIS OF UNTREATED SYPHILIS

Acute syphilis in adults is rarely lethal and is only occasionally disabling. Nevertheless, it constitutes the first phase of a chronic disease which ultimately results in great morbidity and mortality. When acute syphilis is untreated about 25 per cent of patients will eventually attain a state in which no clinical or serologic evidence of the disease is manifest ("spontaneous cure"), about

25 per cent will die of other causes than syphilis, about 15 per cent will have serologic (blood serum) evidence of syphilis but will remain otherwise free of sign or symptom, about 12 per cent will experience syphilis of skin, mucous membrane or bone, approximately the same percentage will have cardiovascular syphilis, and a slightly smaller percentage will have neurosyphilis (fig 2). In summary, somewhat less than 25 per cent will eventually die or become incapacitated by syphilis, about 12 per cent will have relatively benign active syphilis and the remainder will experience no personal menace to health from the disease.<sup>14</sup>

Latent syphilis, by definition, indicates infection without clinical signs or symptoms of disease in patients with normal spinal fluid. At the outset it should be stated that, so far as the future of the individual patient is concerned, untreated latent syphilis will by no means invariably terminate in crippling or devastating disease. It will be seen that the chief difference between the ultimate prognosis of untreated latent syphilis and that of untreated acute syphilis is due to the fact that a considerable number of patients with acute syphilis never attain latency according to the foregoing defini-

Fig. 3—Outcome of untreated latent syphilis

tion of this term. This is due to the presence of neurosyphilis. When true latency becomes established, neurosyphilis will rarely evolve. The Cooperative Clinical Group,<sup>15</sup> prognosticating on the basis of its own and Bruusgaard's experience, surmised that approximately 25 to 35 per cent of patients with untreated latent syphilis ultimately attain clinical cure and that an additional 25 or 35 per cent will have no evidence of their infection except a positive Wassermann reaction of the blood. The remaining patients with latent syphilis will experience relapses of the acute infection or progression into visceral or cardiovascular disease or disease of the central nervous system (fig 3).<sup>16</sup> Thus approximately two out of three patients will experience no serious results from syphilitic infection. How does this alter the life expectancy of a person with latent syphilis, a person who has neither signs nor symptoms of the disease, whose cerebrospinal fluid is normal and who has only a positive reaction of the blood to indicate the presence of infection? Life expectancy is shortened from that for the general population between the age of 30 and 60 by 17 per cent if the patient is a white male and by 30 per cent if he is a Negro male.<sup>17</sup> A study of 100,000 applicants for life insurance subjected to medical selection and considered favorable except for

13 While a statement of fact this point has no place in clinical therapeutics. The importance of the prompt treatment of all acute syphilis is obvious in the light of its great infectiousness.

a history of syphilis indicated that actual mortality is about 1.4 times the predicted mortality.<sup>18</sup> If the patient is a woman it is probable that her life expectancy will be greater, since the incidence of serious lesions of the central nervous system and cardiovascular involvement is distinctly less in females than in males.<sup>19</sup>

While a relatively small number of untreated patients in Bruusgaard's series acquired neurosyphilis (4 per cent), it should be emphasized that routine studies of the cerebrospinal fluid were not made, and the material thus loses much of its value. Kemp and Menninger<sup>20</sup> pointed out that over 50 per cent of 680 patients who had received no treatment gave clinical or laboratory evidence of neurosyphilis. They noted but little difference in incidence between the sexes, males showing only a slight increase over females. While this observation indicates that signs and symptoms referable to the central nervous system commonly develop in the course of syphilitic disease it is reassuring to point out that less than 10 per cent of all patients with acute syphilis (including both white patients and Negroes of both sexes) actually acquire clinical neurosyphilis and that only 1 or 2 per cent who complete the acute phase of the infection with normal cerebrospinal fluid (i. e., attain latency) face this threat

Fig. 4—Effect of syphilis on pregnancy. A outcome in absence of maternal syphilis. B outcome in presence of maternal syphilis.

An analysis of data dealing with the probable outcome of latent syphilis in relation to cardiovascular disease<sup>16</sup> indicated that from 10 to 15 per cent of patients will experience this complication. Unquestionably the incidence of cardiovascular syphilis is greater for males than for females. This is true both in the Negro and in the white race. I do not feel certain that the Negro male is more susceptible than the white male to the development of cardiovascular syphilis. It may well be that the high incidence of cardiovascular disease in Negro men is due to the great frequency with which syphilis occurs in this group and not to increased individual susceptibility to syphilitic cardiovascular involvement.

The latent state is terminated and "benign" lesions of skin, mucous membrane and bone eventually develop in from 10 to 15 per cent of untreated patients with chronic syphilis.<sup>16</sup> While these constitute an important cause of morbidity they rarely result, if uncomplicated, in mortality.

Syphilitic disease of the liver, esophagus, stomach, rectum, mediastinal structures, lung, kidney or hematopoietic apparatus occasionally terminates the latent state

(0.5 to 1 per cent) but these conditions develop infrequently to be of importance in a general consideration of the prognosis of the disease.

In a discussion of the prognosis of latent syphilis Moore<sup>7</sup> summarized the matter as follows. Assuming that the disease has existed for four years and in latency has been attained, with negative results of physical examination and tests of the cerebrospinal fluid if the patient receives no treatment:

At best it is probable that he has only two chances out of ten of developing serious trouble, at worst not more than the chances out of ten. If lesions do occur, there is probably a worse than an even chance that they will be incapacitating and cardiovascular involvement is the chief serious risk which must be feared. The danger of the development of neurosyphilis (probably excepting only a more or less pure vascular involvement) is largely past by the time true latency in the sense in which I have used the word, is achieved.

#### THE PROGNOSIS OF UNTREATED SYPHILIS IN PREGNANCY

Since approximately 10 per cent of all syphilis is thought to be congenitally acquired, it is a matter of no small importance to consider syphilis as a factor in pregnancy and to determine what the outlook for the product of conception is when syphilis exists.

Experience indicates that, when infection is acquired at approximately the same time at which conception occurs, fetal syphilis will almost invariably result. It is difficult to see how fetal infection could fail to develop in the presence of generalized maternal infection, since the inciting agent of the disease is distributed throughout the body (spirochetemia). It is likewise difficult to see how with the same circumstances prevailing a pregnant woman infected in the seventh or eighth month of gestation could fail to infect the placenta or fetus, although apparently normal infants are born under such circumstances. Although evidence of infection may develop in these infants after birth, it has been attributed to infection during passage through the birth canal and nursing rather than to intra-uterine contamination with the virus. One wonders whether this paradox may not in many instances be explained by the existence of an intra-uterine lag or prolonged incubation period in the maturing fetus rather than by postnatal infection.

The observations of Jeans<sup>6</sup> and of the Cooperative Clinical Group<sup>8</sup> give accurate data relative to the incidence of syphilis in children born of women who have passed through the acute stage of the disease and are considered to have latent infection. Moore<sup>7</sup> presented this material in an impressive way (fig. 4). It is seen that when women with syphilis become pregnant the products of conception face an extremely hazardous future. From 30 to 50 per cent of such pregnancies terminate in miscarriages or stillbirths. From 18 to 30 per cent of the pregnancies result in viable offspring who do not survive infancy, and from 11 to 24 per cent result in infants with syphilis. Only 17 per cent of pregnancies in syphilitic women will result in healthy nonsyphilitic offspring who survive infancy. When these figures are compared with those for the outcome of pregnancy in nonsyphilitic women, the enormous importance of syphilis as a cause of fetal and infant mortality is apparent, and this in spite of what seem to be high figures for miscarriages, stillbirths and infant mortality for the "normal" group. Moore tersely made the contrast: "A syphilitic woman, untreated, has only

one chance in six of bearing a live, healthy infant as compared with the normal woman's three chances in four."

#### THE PROGNOSIS OF TREATED SYPHILIS

It has already been stated in this discussion that acute syphilis acquired in adult life rarely kills. It is, nevertheless, highly infectious. Persons with acute syphilis, while in no immediate danger of their lives, are passing through an experience which renders them dangerous to their intimate personal contacts. They make up the group which keeps the epidemic of syphilis raging. In the final analysis they are responsible for the 500,000

TABLE 1—Results of the Best Present Day Treatment of Early Syphilis (Moore)

Stage of Syphilis	Chance for Cure Percentage
Seronegative primary syphilis	100
Seropositive primary syphilis	95
Early secondary syphilis	99.95

new cases which appear annually in the United States,<sup>21</sup> for the man or woman with acute syphilis constitutes the medium by which the spirochete passes to its next victim. The importance of this from the point of view of the public health can hardly be overemphasized. Furthermore, the patient with acute syphilis is in an extremely critical position with regard to his own future. This is true because it is during the acute stage of the infection that the chances are best for absolute "cure." It is apparent then that the patient with acute syphilis should not be reassured regarding his situation by the statement that he will survive the acute infection. On the contrary, he should be sensitized to the fact that he is a grave menace to his intimate associates and that the best chance for completely ridding himself of his infection exists only during its acute phase. His situation is indeed critical from the point of view both of his fellow man and of his own future. What does treatment offer him? Stokes and his associates<sup>22</sup> have considered this question in the light of data obtained from several large syphilis clinics.

The figures in table 1 are Moore's<sup>7</sup> and represent the results obtainable only if patients cooperate fully, are treated expertly and bear treatment well. Under these circumstances "cure" may be obtained in from 90 to 100 per cent of cases. Granting that such ideal conditions frequently do not obtain, it is nevertheless clear (table 2) that, if the patient remains under medical observation, regardless of the amount and type of treatment administered the chances for good results are most encouraging.

It is obvious that the best treatment of late syphilis is the prevention of its development by curing early syphilis. This cure may be accomplished in 90 per cent of cases which come under observation during the acute stage of the infection. The all important fact to the patient that acute syphilis is "curable," together with the fact, equally important to the public health, that it is rendered noninfectious by treatment, places early syphilis directly in the spotlight of medical attention and effort.

It has been stated that it is difficult to obtain that degree of cooperation from patients with syphilis which insures proper, adequate treatment. What of those who

receive inadequate treatment? It has been clearly demonstrated that inadequate treatment often reacts unfavorably on the course of the disease. The data supplied by the Cooperative Clinical Group indicate that 13 per cent of patients inadequately treated (less than twenty injections of arsphenamine) have recurrences of acute infectious lesions, whereas only 2.7 per cent of patients who receive twenty or more injections experience such recurrence. The reappearance of infectious lesions of the mucous membrane and skin after cessation of treatment represents concrete evidence (1) that the virus is not wholly eradicated (inadequacy of chemotherapy) and (2) that the patient is unable to suppress or control those organisms which survive chemotherapy (inadequacy of immunity). If no treatment at all is given the patient with acute syphilis, immune forces will in time convert the generalized infection into a focal one. When this occurs, immunity is usually effective or "solid" enough to prevent the recurrence of the acute infectious lesions. If the natural development of this resistance to infection is interfered with by chemotherapy, it is a matter of the greatest importance that treatment be continued until the infection is entirely eradicated. If it is withdrawn short of this, the patient may be deprived of the benefit of naturally acquired resistance to infection without attaining eradication of the infection. Recurrences of acute manifestations of syphilitic infection under such circumstances are by no means confined to the skin and mucous membranes. The mucocutaneous lesions are serious, for they spread disease, but they are not the source of physical incapacity or death of the patient. More serious are the acute exacerbations of syphilitic infection which occur in the nervous system (meningitis, involvement of cranial nerves).<sup>23</sup>

While it seems probable that so far as the individual patient is concerned no treatment is better than inadequate treatment for acute syphilis, this point of view certainly cannot be given consideration in practical ther-

TABLE 2—Results of Treatment, Without Relation to Amount and Type of Early Syphilis (Moore and Cooperative Clinical Group)

Stage of Syphilis	No of Patients Treated	Satisfactory Clinical Outcome Percentage
Seronegative I	140	71.4
Seropositive I	274	53.3
Early II	912	49.8

apeutics. The spread of syphilis is dependent on the existence of untreated acute syphilis. Therefore every patient with acute syphilis should be treated promptly regardless of the number of injections it may be possible ultimately to administer. A few treatments render acute syphilis at least temporarily noninfectious, and the majority of patients who have been thus rendered noninfectious will remain so even though they discontinue therapy long before obtaining the best ultimate result.

The prognosis of acute syphilis adequately treated, untreated and inadequately treated has been studied by Moore, and table 3, from his monograph, illustrates the points which have been emphasized in this discussion.

What has treatment to offer in the case of latent syphilis? The person with latent syphilis is free of symptoms and signs of disease and has only a positive Wassermann or flocculation reaction of blood to show for his infection. In the large number of cases of latent syphilis studied by the Cooperative Clinical Group the effect of treatment is most impressive when evaluated

have symptoms or signs of the infection. Thus the treatment reduces the morbidity, as it does for early latent infection, from 25 to 35 per cent to less than 5 per cent.

What is the outlook for established cardiovascular syphilis and syphilis of the central nervous system? The matter involves individual factors which all but defy statistical approach. These factors render the prognosis of chronic active syphilis a highly individualized problem. That modern treatment has resulted in an improved prognosis for patients with established cardiovascular syphilis, syphilis of the central nervous system and visceral disease is clear, but the subject cannot be dealt with in this discussion. My concern has been to determine the probability of the development of serious manifestations of infection and what can be done to prevent them.

TABLE 3—Estimate of the Probable Outcome of Early Syphilis (Moore)

Type of Syphilis		Probable Outcome, Expressed in Approximate Percentage		
Original Diagnosis	Ultimate Outcome	Untreated	Inadequately Treated	Thoroughly Treated
Early syphilis	Serious late syphilis	25	35-40	5-10
	Benign late syphilis	15	15	5
	Latent syphilis	30	30	5
	"Cure"	30	15-20	50-55

in the light of the probable outcome of untreated latent infection. The figures in table 4 were obtained from Moore's monograph, from a recent publication by him<sup>24</sup> and from the reports of the Cooperative Clinical Group. It is apparent that from 70 to 80 per cent of early latent syphilis is curable in the clinical sense of that word, that less than 5 per cent of properly treated patients with latent syphilis acquire active lesions of chronic syphilis and that these are rarely incapacitating. The excellent prognosis of the treated patient must be attributed to a combination of effective immune forces present in him and the protection obtained by the specific treatment administered. It is therefore apparent that, while the patient who has progressed from the acute into the latent stage of syphilitic infection has forfeited his best chance for biologic "cure" in the strict sense, he has, if he chooses a good physician and if he presents himself within three or four years of the onset of his infection, an excellent chance for symptomatic

TABLE 4—Estimate of the Probable Outcome of Latent Syphilis (Moore, Brunsgaard and Cooperative Clinical Group)

	'Cure %	Latent Infection %	Late Syphilis (Cutaneous Mucous Osseous) %	Cardiovascular Syphilis %	Neurosyphilis %	Other Visceral Syphilis %
Untreated	25-35	25-35	10-15	10-15	12-20	0.5-1
Adequately treated early latent syphilis	70-80	20-20	2-5	2-5	12-20	0.5-1
Adequately treated late latent syphilis	60-70	25-35*	1-6†	1-6†	1-6†

† Lesions rarely incapacitating

and serologic cure. Even if he delays action until he is in the late latent stage he can be given an excellent clinical prognosis. True it is that the Wassermann reaction of the blood may be irreversible (25 per cent), but it has been shown that this need not be seriously considered if the disease has been accurately classified as latent syphilis, i. e., if infection in the central nervous system or cardiovascular apparatus does not exist. If the disease is correctly classified and actually latent, less than 5 per cent of patients properly treated will later

THE PROGNOSIS OF TREATED SYPHILIS IN PREGNANCY

It has been seen that the presence of syphilis in the female creates an extremely hazardous future for the product of conception and that with syphilis the chance for a normal healthy child decreases from approximately 75 per cent to the appallingly low figure of 17

TABLE 5—Syphilis and Pregnancy (Cooperative Clinical Group)

	Living Nonsyphilitic Children Percentage	Syphilitic Children Percentage
Treatment before fifth month	75.4*	91†
Treatment after fifth month	60.6*	23.4*

\* Amount of treatment is not considered only duration  
† At least ten injections of arsphenamine and appropriate heavy metal  
‡ At least ten injections of arsphenamine but less than ten injections of heavy metal

per cent. What does proper treatment of the syphilitic mother do with respect to prenatal and infant mortality? It is difficult to answer the question directly and in a way which allows for comparison with the statistics on untreated syphilitic mothers. The Cooperative Clinical Group<sup>25</sup> furnished impressive figures on the results of treatment of 603 women who had 922 pregnancies after the establishment of their syphilitic infections. These figures, which indicate the results of varying amounts of treatment given for varying periods, are shown in table 5.

Adequate treatment started before the fifth month was followed by the birth of a living nonsyphilitic child in 91 per cent of the cases. Similar results were reported by Ingraham<sup>26</sup> and others. This observation indicates that congenital syphilis is from a practical point of view a preventable disease. Recognition of syphilis early in pregnancy and the administration of adequate standardized treatment will for practical purposes eradicate congenital syphilis. "Prevention is dependent upon the routine, early and repeated use of the serologic blood test on every pregnant woman and upon adequate early treatment once the diagnosis of syphilis has been made." Furthermore, when the presence of syphilis in the pregnant woman is not recognized until late in pregnancy, many more living

nonsyphilitic children will be born if vigorous treatment is instituted than if inadequate therapy or no treatment is employed.<sup>27</sup> If early syphilis appears late in pregnancy and no treatment is instituted, the loss of fetal life may be as great as 46 per cent. This figure, according to the observations of the Cooperative Clinical Group, is reduced to 7.6 per cent when treatment is employed. These considerations make it apparent that no clinical aspect of syphilis offers a more challenging and at the same time promising problem to the clinician than syphilis in pregnancy.

## SUMMARY

It commonly occurs that syphilitic infection becomes established without manifestations of the acute stage of the disease. The recognition of its presence is then dependent on either serologic tests or the ultimate evolution of serious sequelae. The incidence of cardiovascular syphilis and serious involvement of the central nervous system appears to be greater in patients who fail to react at the time infection occurs with acute lesions of the skin and mucous membrane than in those who experience these lesions. Thus asymptomatic infection seems particularly disposed to the ultimate development of serious sequelae. The frequency of asymptomatic infection in the female renders the general recognition of its presence and the prevention of congenital syphilis impossible without the employment of serologic tests of all pregnant women.

The threat of untreated syphilitic infection to the individual is great. It constitutes a menace to personal contacts, the earlier the infection in terms of elapsed time from the initial lesion, the greater the menace. The pregnant woman with untreated syphilis has only one chance in six for a healthy living infant as compared with the normal woman's three chances in four. There is some evidence that age, race and sex are factors in determining the morbidity and mortality of syphilis. Syphilis in infancy is commonly fatal. In adult life the Negro male seems to be in a particularly vulnerable position with regard to cardiovascular syphilis and the white male with regard to neurosyphilis. The infection is less likely to result in serious disability in women, yet syphilis in pregnancy constitutes an extremely serious problem.

With treatment acute syphilis can be rendered non-infectious and "cured," and with the best treatment "cure" is possible in from 90 to 100 per cent of patients. From 70 to 80 per cent of patients with early latent syphilis can be "cured" in the practical sense of that word. The treatment of late latent syphilis is of the greatest importance, since it greatly reduces subsequent morbidity and mortality from cardiovascular and benign tertiary syphilis. The early recognition and proper treatment of syphilis in pregnant women will greatly reduce prenatal and infant mortality and almost completely eradicate the tragic problem of congenital syphilis.

The outlook for the patient with syphilis is dependent in no small way on the physician who first discovers the disease. With the foregoing considerations in mind the physician may approach the therapeutic problem with confidence and optimism—qualities sorely needed by both patient and physician during the long months necessary if treatment is to be adequate.

## THE TREATMENT OF INFANTILE ECZEMA

FROM THE POINT OF VIEW OF  
THE ALLERGIST

BEN Z. RAPPAPOORT, M.D.

AND

RUDOLPH HECHT, M.D.

CHICAGO

*This is the last of a series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee on Revision and The Journal of the American Medical Association.—Ed*

Although attempts at differentiation and classification of disease processes are of value, in infantile eczema these are difficult and, in fact, almost impossible because one type merges into another and because several conditions may be present at the same time. One is tempted to agree with Moro that "Ekzem ist was, aussieht wie ein Ekzem" (Eczema is what looks like eczema). The longer one deals with infantile eczemas, the more one concludes that classifications have restricted values and that differentiation is possible only after prolonged observation of the course of the eruption and its response to therapy.

The great impetus given to the study of eczema came with the introduction of the concept of allergy and the subsequent demonstration that some of these conditions depended on a specific sensitization mechanism. It has been in the infantile eczemas that the best results have been attained by the cooperation of the pediatrician, the dermatologist and the allergist.

The important conditions considered under the head of infantile eczema are (1) seborrheic dermatitis, (2) fungous infections, (3) contact dermatitis and (4) atopic dermatitis. The clinical appearance and course of these conditions have been discussed in detail by Sulzberger.<sup>1</sup> The discussion here will be limited to the contact type and atopic dermatitis.

## HISTORY AS AN AID IN DIAGNOSIS

If we were limited in our practice to only one diagnostic medium, of all those available we would choose the history. A carefully taken history usually gives leads that point to the proper avenue of investigation, doing the indicated tests makes the diagnosis possible. The allotted space permits brief mention of only a few of the pertinent details to be elicited. These are as follows: Onset, course and duration of present complaint, age at onset, its first site, its appearance at onset, dry? wet? vesicular? erythematous? scaling? the degree of itching? (itching in atopic dermatitis is intense), sites and mode of spread, diet at onset (detailed and as exact as possible, was a new food added at onset?), present diet, foods that cause erup-

This is the last of three articles on this particular subject. From the Department of Medicine, University of Illinois College of Medicine and the Mandel Clinic, Michael Reese Hospital.  
<sup>1</sup> Sulzberger, M. B. The Treatment of Infantile Eczema from the Point of View of the Dermatologist. J. A. M. A. 112: 38 (Jan. 7) 1939.

tion to flare up, diet manipulation in detail (if certain foods were supposed to have been eliminated, it should be ascertained whether this was done completely), internal medications, topical medications (did eruption get worse after any of these?), environmental conditions, details of room furnishings, clothing, toys, insecticides, pets, cosmetics of attendants (does the rash get worse when the child is handled by some member of the family?), effect of removal from home, results of previous tests, occupations and hobbies of members of the family, atopic family history (suggesting that the condition is atopic)

This is by no means complete but indicates the method of questioning that must be adapted to the particular case. The more accurate and painstaking the history, the more likely that certain 'leads' will be obtained to guide one in the diagnostic procedures to be described.

It is due mainly to the work of Sulzberger,<sup>2</sup> Bloch<sup>3</sup> and Jadassohn<sup>4</sup> that a clear understanding has been obtained of some of the underlying processes and their correlation with the observed clinical phenomena. It is well to recall that the upper layers of the epidermis are relatively impermeable and that the epidermis has no blood vessels while the upper cutis is richly supplied with them. These facts may be correlated with clinical, experimental and histologic studies as follows:

**Contact Dermatitis**—The "shock tissue," i.e. the site of reaction, in contact dermatitis is primarily the epidermis. Histologically it is known that the primary lesion of the epidermis is edema, which can be interstitial and/or parenchymatous and eventuate in vesicle formation. Clinically contact type dermatitis is characterized by vesiculation. According to Sulzberger, the substances that are likely to call forth this condition are:

1 Substances that are soluble having small molecular weight and rapidly moving ions which are capable of penetrating the horny layer. Examples are metallic salts such as nickel and mercury.

2 Substances soluble in the fat of the skin, such as the fatty substances of plants, e.g. ivy and ragweed oils.

3 Substances that have an affinity for horny material and firmly bind themselves to the horny layer of the skin, e.g. dyes.

4 Anesthetics that have an affinity for ectodermal tissue and fat, e.g. procaine hydrochloride and ethyl aminobenzoate.

5 Primary irritants, such as fat solvents, soaps, alkalis and acids.

The reactions given by the substances of the first four groups are of an allergic nature, i.e. specifically acquired reactions, in which no antibodies have as yet been demonstrated. The materials in group 5 usually act by means of a primary irritant effect on the epidermis, although typical allergic sensitization can here occur.

Having made the diagnosis of contact type dermatitis by history and clinical characteristics, one makes test by applying the substance directly to the epidermis by means of the patch test.

To do a patch test a small square of adhesive is used on the center of which has been placed a small square of cellophane. The material to be tested is placed on a still smaller piece of linen. The patch is removed in forty-eight hours, unless the itching becomes intense before this time has elapsed, in which case the patch is removed sooner. A positive reaction is characterized by an erythematous, papular, vesicular or lous eruption corresponding to the area occupied by the square of linen. Sometimes the reaction is delayed and may appear later. It is well, therefore, to examine sensitive sites for several days after removal of the patch. One must ascertain that the material in the concentration used is not a primary irritant. A positive reaction, however, is not proof that this is the substance causing the clinical symptoms unless removal of the material from the patient's environment results in improvement and its subsequent presence causes an exacerbation.

Positive reactions to patch tests with substances of high molecular weight such as proteins are practically unknown in adults, perhaps owing to the fact that they are unable to penetrate the epidermis. In infants one does occasionally obtain positive reactions to patch tests with wool, feathers, silk and even food proteins, especially egg white. Whether this is from the great permeability of the infant's skin or some other peculiarity of infants is not known. Moreover, it is unknown whether these reactions are the exact equivalents of the contact type, typical, eczematous reactions produced by patch tests. It is well known that woolen garments frequently cause an exacerbation of the eruption even in infants suffering from a dermatitis not based on specific sensitization. Mechanical factors of a non-specific nature are probably just as important as are specific sensitizations in the case of irritations apparently resulting from wool (the Koebner phenomenon which is discussed especially in relation to infantile eczema by Kreibich<sup>5</sup>). To rule out possible contact type dermatitis caused by protein substances, it is well to make patch tests on infants with suspected foods and inhalants. The diagnosis in many of these cases is largely made in an inferential fashion. If the family history is negative for atopy, if scratch or intracutaneous tests give negative results, if reactions to patch tests are positive, if eosinophilia is absent and if exposed surfaces are involved, the diagnosis of contact dermatitis may be tentatively made.

**Atopic Dermatitis**<sup>6</sup>—This is by far the most common form of infantile eczema. A family history of asthma, hay fever and other atopies is common. These patients usually have intense itching, eosinophilia and immediate wheal reactions to scratch or intracutaneous tests with the usual protein allergens, frequently have passive transference antibodies (reagins) and typically fail to give classic reactions to patch tests with contact substances. In a classic case the condition comes on in the third month and subsides usually by the end of the second year. A large number of these infants become free from atopic stigmas after the second year of life. However, some do not clear up and gradually

are transformed into the adult type of atopic dermatitis (disseminated neurodermatitis). Associated with this there may be hay fever, asthma and other atopies in various combinations. It is difficult to follow these patients for the time necessary to gain a complete picture. While most of them recover completely by the end of the second year and have no subsequent atopic diseases, in some these disturbances develop later, and in others cutaneous disorders last without interruption from infancy to middle life. It is noteworthy that many young persons with hay fever or asthma who present themselves for treatment give a history of infantile eczema.

The atopen to which these patients are sensitive acts on the vessels of the upper cutis. To test these vessels (the shock tissue) the substance must be brought to them. This is accomplished by means of the scratch or intracutaneous test. The test substances are usually proteins.

#### CUTANEOUS TESTS

The child should be tested with those foods which he is eating or has eaten. The common foods included in such tests are wheat, corn, rice, barley, oats, egg, milk, potato, tomato, carrots, peas, string beans, spinach, asparagus, banana, apple, orange, prunes (plums), apricots, raisins (grapes), beef, chicken, lamb, pork (bacon) and cod fish. If the child is breast fed or partially breast fed, tests may sometimes be necessary with those foods frequently eaten by the mother in addition to those in the child's diet.

Environmental substances, however, present a different problem, since most American homes have a variety of possible inhalant and contact materials. We test with a rather large list of environmental materials: feathers, wool, silk, dog dander, cat dander, rabbit dander, goat dander, cattle dander, hog dander, horse dander, house dust, cottonseed, linseed, krapok, orris root, pyrethrum and pollens (in older children, especially if worse in summer).

Many of the materials listed are not easily identified in their commercial use. Rabbit hair does not necessarily signify a live, hopping rabbit but more frequently an angora trimmed garment or a fur covered toy. Cattle hair may be woven in the Chinese rug on which the baby plays or in the pads under the carpets. Because of the obscure uses of many of these substances it is wise to resist the temptation of omitting tests in the absence of a history of exposure to these common inhalants. If a positive reaction to a substance is found, one must search diligently for the presence of the material. While in infants (up to 1 year of age) inhalants are seldom the causes of atopic dermatitis, there are a few for whom such atopens as feathers are important factors and whose condition is improved on their elimination. Peck and Salomon<sup>7</sup> found reactions to feathers in infantile eczema, and when positive reactions to patch tests were present they obtained definite improvement on removal of the feathers. Rostenberg and Sulzberger<sup>8</sup> have published some interesting tables on the results of patch tests with foods and inhalants in infantile eczema. In atopic dermatitis, patch tests with foods and inhalants are done only in infants up to 1 year of age. These are of no value in older children with typical atopic dermatitis.

**Technic of Tests**—For scratch tests commercially prepared dried extracts may be used. After the site has been washed with alcohol an instrument is used which makes six superficial scratches painlessly at one time. A circular borelike instrument described by Hill is simple, safe and relatively painless for this purpose. All scratch tests may usually be done at one visit with safety. These are done wherever clear skin is available, usually on the anterior aspect of the thigh in infants. A drop of twentieth-normal sodium hydroxide solution is placed on each scratch. Into this the allergen is gently rubbed with a toothpick. As a control, a drop of twentieth-normal sodium hydroxide solution is rubbed over one of the scratches and the other tests are compared with this. The sites should be observed frequently for the next thirty minutes. First there is usually a traumatic area of redness around the scratch. This subsides shortly and is followed in the area of a positive reaction by a slowly increasing redness which, in strong reactions, surrounds a wheal. This may develop any time from a few minutes to half an hour.

Intracutaneous tests are done only with those substances which give negative results on a scratch test. If a scratch test with a substance is definitely positive, it need not and it must not be used intracutaneously. When the intracutaneous technic is used an entire botanically related group should not be injected at one visit, e.g., the cabbage group (broccoli, cauliflower, turnips, brussels sprouts, cabbage and so on). Members from different groups should be selected to avoid constitutional reactions. For this reason further tests are discontinued for that day if several large reactions develop. Epinephrine solution (1:1,000) and a sterile syringe and needles must be at hand to combat a reaction. The intracutaneous wheal raised by the material injected (0.02 cc.) should not be more than 2 mm. in diameter. Twelve tests are usually done at one visit. The ordinary method of performing these is by means of a 26 or 27 gage needle on a tuberculin syringe. By observing all these precautions, one should be able to avoid untoward effects with the intracutaneous method.

Experience is necessary for the interpretation of the tests. What may be etiologically a clinically significant reaction in one person may be without clinical significance in another. In infants the reactions are often very slight and controls are essential. Here a scratch test with a definite erythema without redness at the control site should be considered positive. The formation of wheals with erythema is more significant. Positive intracutaneous reactions are larger than positive reactions to the scratch test. Positive reactions in infants, if correctly "read," are of more clinical value than in adults. The exception to this, which will be discussed later, is the reaction to egg white. Scratch tests, when positive, are more significant than intracutaneous ones because a higher degree of sensitivity is indicated and the errors are more easily avoided from insufficient experience in interpretation, improper technic, irritating materials and the occasionally highly reactive skin. No positive reaction can be considered significant, however, unless clinical trial proves its relationship to the dermatitis. Cutaneous tests are important aids and not the final means for diagnosis.

**Trichophyton or Tuberculin Type of Reaction**—The shock tissue is the upper cutis and the cutis. The test is elicited by injecting intracutaneously 0.1 cc. of properly diluted micro organisms or their products.

<sup>7</sup> Peck, S. M. and Salomon, Gustav. Eczema of Infancy and Childhood. *Am. J. Dis. Child.* 46: 1308 (Dec.) 1933.  
<sup>8</sup> Rostenberg, Adolph, Jr. and Sulzberger, M. B. Some Results of Patch Tests. *Arch. Dermat. & Syph.* 35: 433 (March) 1937.

The resultant response is of the delayed type and comes on after from twenty-four to forty-eight hours. Characteristically the positive reaction is a papule with an area of surrounding edema and erythema, although immediate reactions of the wheal type have been reported.<sup>9</sup> When fungous or yeast infection is suspected it is well to test with trichophylin and oidiumycin extracts.

#### THE IMPORTANT ALLERGENS IN INFANCY

**Foods**—Egg occupies a peculiar position in infantile eczema. As a result of the reactions to egg many perplexing questions have arisen. On the other hand, many important fundamental facts have been uncovered. Most infants with atopic dermatitis when tested with egg white give immediate wheal reactions even though the child has never ingested egg. This is a true immunologic reaction as demonstrated by the presence of reagins in the patient's blood. Sensitization to egg probably occurs in utero by way of the placenta. It has been shown that unaltered egg antigen is capable of entrance into the circulation<sup>10</sup> and into mother's milk and thus may be transmitted to the infant. These infants may therefore have had previous contact with egg, and the reaction can be looked on as a typical allergic reaction. It is significant, however, that some infants without eczema give positive cutaneous reactions with egg white antigen. This finding is of great importance and has prompted the formulation of the theory that many infants on their first contact with a food may become sensitive to it, i. e. develop antibodies (precipitins, cutaneous tests). The subsequent ingestion of the food renders the normal infant immune and the antibodies disappear. Instead of achieving the normal state of immunity, the atopic child remains sensitive to this food. Since most infants who have atopic dermatitis and who give a positive cutaneous reaction for egg have never eaten egg, this finding is of little practical but of great theoretical importance. In older children egg may be a specific factor. For some time we have been testing these with five purified egg white protein fractions, furnished us by Dr. A. G. Cole. Varying reactions were found to the different fractions as well as to fowl meat in some cases. Because of this, when an infant is sensitive to egg we eliminate fowl from the diet while symptoms are present. When the skin clears a clinical test with fowl meat is done, and if no exacerbation occurs it is permitted in the diet.

In infancy milk is the most important article in the diet and the most frequent cause of atopic dermatitis. Cow's milk contains casein, lactalbumin, lactoglobulin and an alcohol soluble protein. These are all immunologically distinct. Casein has been shown to be the common antigen in milks from various species, while the other milk proteins are probably species specific. Casein is not coagulated by boiling and retains its antigenic activity after such treatment. It is a poor antigen according to most investigators, although Wells<sup>11</sup> states that "casein is far more active than some authors have maintained." Hill has come to the same conclusions from clinical observations.

It is known that many ingested substances find their way into milk. As has already been mentioned, milk offers a route whereby a mother can transmit various proteins to her child. The passage of wheat proteins

into cow's milk causing symptoms in a wheat sensitive infant has been suggested.<sup>12</sup> In the breast-fed infant a thorough history of the foods which the mother eats is essential. In the case of the infant fed on cow's milk one must consider the fodder used in the particular locality as a possible additional factor in the etiology of obscure cases. Cattle fodder may contain large amounts of cottonseed, flaxseed, wheat and soy beans. Whether any or all of these are present in the milk in sufficient amounts to cause trouble is an unsettled question.

It is probable that the infant is most often sensitive to the lactalbumin or globulin, although Hill maintains that casein sensitization is not altogether uncommon. Thus an infant on a formula of cow's milk will frequently be improved by milk that has undergone prolonged boiling. This coagulates most of the albumin and globulin. Positive reactions to scratch tests with milk are infrequent, although intracutaneous tests with milk proteins are not uncommon.

Wheat is the most frequently ingested cereal and among the cereals gives the most frequent cutaneous reactions. Here too the role of common antigens is important, i. e. a patient sensitive to wheat may also be sensitive to a common antigen found in rye. Chemically and immunologically it has been shown that there are apparently two rather distinct groups of cereals—the wheat group (wheat, rye, barley, durum and the like) and the corn group (maize, sorghum and so on). There are probably common protein constituents within each group, although the two groups are apparently quite distinct. When there is evidence of sensitization to cereals or when cereals are eliminated from the infant's diet, one must, in the breast-fed infant, take into account the possibility that the mother's and cow's milk contain the cereal antigens also.

Orange rarely gives a positive reaction in the scratch test and only occasionally in the intracutaneous test, although one frequently obtains a history of an increase in the severity of symptoms on its addition to the diet. If orange is omitted, other fruits or ascorbic acid should be used to avoid vitamin C deficiency. Fish sensitization, especially cod fish, has been reported.

**Environmental Substances**—The evidence on hand would seem to indicate that in infants these materials can occasionally cause eczema by three or possibly four routes: (1) by inhalation and entrance into the circulation by way of the lungs, (2) by contact, a contact type eczema being produced, although on an excoriated skin the inhalant allergen may enter and be effective through the circulation, (3) by transepidermal penetration through the intact skin, (4) possibly by inhalation and swallowing of allergen with sensitization by way of the gastrointestinal tract.

#### SPECIAL DIAGNOSTIC PROCEDURES

**Passive Transfer**—When the infant has such a generalized eruption that no clear skin is available for tests, and if a careful history and elimination diets have not resulted in clinical improvement, passive transfer tests are used for diagnosis. The child's serum is injected into numerous sites on a normal skin, and these are tested with the various allergens after forty-eight hours. Matthew Walzer uses this method of testing many of his atopic dermatitis patients, because he believes that their skin is altered to such a degree as

<sup>9</sup> Sulzberger, M. B. and Kerr, P. S. *J. Allergy* 2: 11 (Nov.) 1930.  
<sup>10</sup> Walzer, Matthew. *J. Immunol.* 11: 249 (April) 1926.  
<sup>11</sup> Wells, H. G. *The Chemical Aspects of Immunity*. New York: Chemical Catalog Company, 1929.

<sup>12</sup> Balyeat, R. M. and Bowen, Ralph. *Allergic Diseases*. Philadelphia: F. A. Davis Company, 1936.

not to give valuable reactions. He has been successful in clearing up many obstinate cases by using this method.

*Special Extracts*—In a few patients in whom the studies mentioned here have failed to elicit the cause of the trouble, we have been successful with a method suggested by Bret Ratner. This applies only to environmental substances. The mother is questioned carefully for all possible suspected causes, no matter how remote they may appear. A sample of each of these is soaked overnight in twentieth-normal sodium hydroxide solution and scratch tests are done with the supernatant fluid.

#### DIAGNOSIS BY MEANS OF ENVIRONMENTAL AND FOOD STUDIES

The management of infantile eczema can be accomplished in most cases without the use of cutaneous tests. Environmental change sometimes produces results which amaze both the physician and the parents. Removal of the patient to a hospital room furnished with a horsehair or rubber encased mattress can by one simple procedure eliminate a complicated environment of overstuffed furniture, toys, cotton mattress, rugs, cosmetics, animal emanations, dyes and a variety of other substances too numerous to mention. If improvement occurs it is likely that one or more of these environmental substances is the cause. The effect of bringing suspected materials in the presence of the infant can then be studied. One must keep in mind, however, that exposure to suspected substances must be sufficiently long to reproduce the conditions in the home. This may not be practical. From a clinical point of view this type of study, while more difficult and tedious, is much more significant than cutaneous tests. The reason for frequent rapid improvement on hospitalization is not established, but it seems probable that one or more of the environmental home allergens has been the cause in such cases.

Similarly, an organized study, preferably in an "allergen free" environment, can be carried out by means of "elimination diets." Since milk and wheat are the commonest causes of atopic dermatitis, they should be eliminated first. It is necessary at this point to emphasize that multiple rather than single food sensitivity is usually present. Thus while such foods as fish oils, orange, tomato, the various cereals, fruits and vegetables in a large group of cases may be less important than milk and wheat, any or several of these may be the all important foods in the particular patient studied. All foods eaten must therefore be known. All must be suspected.

In most cases, because of the possibility of multiple sensitivity, wheat, milk and eggs should be removed at one time. In the infant this should not lead to any difficulties. Milk can be eliminated or, in the presence of malnutrition, replaced by evaporated cow's milk, milk boiled for two hours and skimmed or evaporated goat's milk. Sensitivity is in most cases to the whey proteins, and these are sufficiently altered by treatment with heat to make them nonallergic for any but the most sensitive patient. Since casein is not altered by heat, such a substitution will not improve the unusual patient who is sensitive to casein. One of the milk substitutes, such as soy bean products or almond-lac, may then be tried. Eggs need no substitution, while wheat may be replaced by corn, oatmeal, sago or tapioca prepared

with water and sugar. Such substitution should result in improvement if the foods permitted are not among the causative factors.

*Food Diaries*—An intelligent mother is in many cases the most important factor in a successful diagnosis. During the study it is desirable to have the mother understand the rationale for the various procedures. She should be taught to keep a carefully itemized diary of each meal and to record any flare-up of the eruption. If the condition becomes worse after certain meals, one or several foods may be found to be the common factors in these meals. They may then be eliminated or replaced and the effect noted.

*Prophylactic Management*—Prophylactic care should not be considered either far fetched or fanciful in atopic families. It is common in our practice for the mother who is under allergic management to inquire what may be done to prevent the occurrence of allergic symptoms in an infant. The difficulty of determining the effectiveness of the measures does not diminish their importance. Certain environmental and dietary precautions can readily be taken in those infants with a family history of atopy. Regarding the environment, if a new mattress is needed it should be made of horsehair. This material, as prepared for such purpose, will not cause symptoms even in those sensitive to horse dander. If a cotton mattress is already in use, it should be sealed with a rubberized cover. If pillows are used, they should be completely encased in rubberized cloth. Old blankets that have had frequent washings are preferable to new ones. They should be covered with sheets so that no wool comes in contact with the child's skin. Contact of wool with the skin should otherwise be avoided. "Snow suits" are not uncommonly the cause of dermatitis in infants. The clothing next to the skin should be smooth, of linen or cotton. Irritation of the skin from other sources should be avoided. Upholstered furniture, dust gathering draperies and, if possible, carpets should not be used in the child's room. Animal pets should not be permitted.

Prophylactic food measures are not only more important but also more readily accomplished. From an immunologic point of view the rationale of the measures recommended depends on two facts: first that the gastrointestinal tract of the newborn infant is highly permeable, and second that denatured proteins are in general nonantigenic and more readily digested than are native proteins. That the gastrointestinal tract of the infant in its first weeks of life is highly permeable is indicated by the appearance in the urine of the proteins of colostrum if the infant nurses while this is secreted. In infants fed on cow's milk during the first weeks of life lactalbumin is found in the blood together with antibodies for this protein.<sup>13</sup>

With these facts in mind, the following precautions should be observed, especially in infants with an atopic background. During the colostrum period if a milk formula is used it should be prepared from evaporated milk. The heating of coagulable protein makes it insoluble so that it loses its antigenicity. Absorption therefore does not occur until it is digested by the gastrointestinal enzymes. While only the whey proteins are coagulable, these are the commonest causes of sensitivity to milk. It seems advisable to use evapo-

rated milk for the infant with atopic background not only during the colostrum period but also subsequently during the first year of life

The next period in the infant's feeding that requires caution is when other foods are added to the diet. We would recommend that foods should be added singly rather than as mixtures. When wheat is added it should be definitely as wheat rather than in a cereal mixture. The one objection to the commercially prepared cereal mixtures is that they frequently contain many ingredients. Unfortunately cooking will not accomplish for wheat what boiling does for milk. If symptoms develop after she starts on a single cereal, the watchful mother quickly suspects the cause of the trouble. The diet can be increased almost as rapidly in this way as by the use of mixtures.

It is our belief that egg white should not be added to the diet until after the first year in infants with an atopic background. It should be thoroughly coagulated before it is given. A simple way of producing a high degree of coagulation of egg white, rendering it easily digestible, is to drop it slowly into boiling water with constant stirring. This produces a finely divided coagulum.

*Active Management*—Dietetic treatment of the atopic infant from the point of view of the pediatrician is discussed in greater detail by Dr. Hill.<sup>14</sup> Here we emphasize the subject briefly from an immunologic point of view. What has been said under diagnosis and prophylactic care applies to the active management. Once the etiologic diagnosis has been determined, the management is not difficult. Most infants will tolerate foods to which they are sensitive if these are thoroughly denatured. We have never found it useful or necessary to give infants injections either of inhalants or of foods for immunizing purposes. Nor has oral immunization proved of value in our hands. It has been our experience that a spontaneous tolerance develops in most infants usually in a few months if the offending food is completely removed. It may be added in a well cooked state, in minute amounts which are gradually increased, with constant surveillance several months after the condition has cleared completely. The exception to this rapid gain in tolerance is found in patients sensitive to egg white. They have a tendency to remain sensitive to the material for much longer periods than to other foods.

Inhalants should likewise be removed rather than injected. Even such a ubiquitous and necessary substance as wool may be replaced in cold weather by cotton clothes made of closely woven poplin or gaberdine cloth, "suede cloth" (cotton), chamois jackets and leggings in highly sensitive patients. In those less sensitive, clothes made of refined woollens such as are used for men's suits will frequently answer the purpose. It is not unusual that the symptoms, after having cleared up, will return at a later date. This is explained by the fact that new sensitivities develop in these children. One must watch them "like a hawk," and when, after a period of improvement, they again have symptoms, the search must again be instituted, provided there has not been some unsuspected break in the regimen.

Local therapy has been omitted from this discussion, as the subject is covered in the papers by Sulzberger<sup>1</sup> and Hill.<sup>14</sup>

## CONFERENCES ON THERAPY

### III DISORDERS OF CARDIAC RHYTHM

*NOTE*—These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and of New York Hospital. The questions and discussions involved participation by members of the college staff, students or visitors. The next report will concern "The Treatment of Edema".—Ed.

The third of a series of conferences on therapeutic was held at the New York Hospital-Cornell University Medical College on Saturday Morning, Oct. 15, 1938 at 12 o'clock, Dr. McKee Cattell presiding.

DR. MCKEE CATTELL. The conference today will be on the subject of the treatment of disorders of cardiac rhythm and will be opened by Dr. Eggleston, who has kindly come here to give the clinical aspects.

DR. CARY EGGLESTON. The arrhythmias, disturbances in cardiac mechanism, constitute therapeutic problems from time to time, sometimes because they actually endanger life but perhaps more common because of the discomforts that they produce in the patients who are their victims.

The commonest of these arrhythmias in ordinary experience is perhaps the simplest of all in its implications, namely, premature beats. These may occur as isolated premature beats, they may arise in the auricle in the auriculoventricular node or in the junctional tissues below the node. They may occur with extreme frequency, they may occur as coupled rhythm, they may occur in runs of many premature beats together sequentially giving rise to a form of tachycardia, or they may occur as an initial premature beat ushering in a run of paroxysmal tachycardia of ectopic origin.

In the treatment of premature beats, one of the first problems to solve, if you can, is that of the mechanism which is responsible for this localized irritation of the cardiac structures that gives rise to a focus of irritability, with a higher rate of impulse production than that of the normal sinus.

There are many poisons, tobacco, coffee and sometimes other poisons, which may produce premature beats. Alcohol, in my experience, is rarely an aggravating factor. Other forms of intoxication, such as absorption from various septic foci of chronic subacute nature, may be responsible. Where one can with reasonable certainty raise a justifiable suspicion as to the possible intoxication which may be present in a patient, the elimination of that intoxication is the first logical step in treatment. That, however, is not a problem of drug therapy primarily.

Theoretically there are several agents that should be helpful in controlling these premature beats, where they are of sufficient importance to the patient to demand control. Practically a very few seem to be of material value. I am going to run over these and leave the discussion of the pharmacology of their actions to Dr. Gold.

Simple sedatives, such as the barbiturates, either actually control the frequency of ectopic premature beats to a greater or lesser extent or else they diminish the patient's sensitivity to them, so that his discomfort is no longer a troublesome factor.

The bromides act similarly and are sometimes quite as useful.

At times the administration of digitalis, probably by virtue of improving the efficiency of the myocardial con-

traction, diminishes the frequency of premature beats and in some patients eliminates them, at least temporarily.

Of course, the one drug that you probably all think of first is that of the quinine group, particularly quinidine, one of the isomers of quinine. Quinidine often controls premature beats. However, quinidine is a potentially dangerous drug, and even with the use of test doses one is not always secure in administering quinidine, though I myself have never had the misfortune of seeing a serious accident result from its administration. The troubles with quinidine are that in the first place a certain number of patients do not tolerate the cinchona alkaloids. They have an idiosyncrasy toward them which bars the successful administration of quinidine. Secondly, in view of the existence of a certain element of danger inherent in the drug itself, one does not always feel justified in running even small risks for the control of a condition which per se is of no material significance to the patient, except with reference to his comfort.

If your judgment dictates that you should use quinidine, then it may be administered in the usual manner of first trying the patient's susceptibility by giving him one or two test doses, usually small in size, seldom more than 0.2 Gm. per dose, two such doses commonly being given at an interval of three or four hours and it being determined whether the patient has any hypersusceptibility. If not, then one may employ quinidine in rising doses until one has administered either enough to control the premature beats or until the patient manifest signs of intoxication. A disadvantage is that while quinidine may control premature beats for a short time it seems in many patients to lose its effectiveness, and the maintenance dose of quinidine employed in these conditions is often futile in permanently or lastingly eliminating premature beats.

Other agents of a pharmacologic nature are scarcely worth mentioning, in my experience.

This leads me to a common disturbance of the cardiac mechanism that is closely related to premature beats, namely ventricular paroxysmal tachycardia, which is not an unusual complication of coronary artery disease, particularly with myocardial infarction. This possibly may be anticipated in a patient with myocardial infarction during the earlier days or weeks following the immediate accident, anticipated by the development of multiple ventricular premature beats, by the development of periods of excessively rapid heart beats, both of which of course should be checked and analyzed electrocardiographically if that is possible.

The administration of adequate doses of quinidine in anticipation of the development of a ventricular tachycardia apparently may prevent the attack. It is important to prevent it as this condition is probably frequently fatal very rapidly—fatal either because of the additional overstrain on an already damaged myocardium or fatal because of the tendency for the condition, under these circumstances, to pass over into a ventricular fibrillation.

It is difficult to assess the actual preventive value of the administration of quinidine under such circumstances because while we may anticipate the possibility of the development of paroxysmal ventricular tachycardia there is no assurance that it would have developed without the quinidine, and there is no ready means of using controls to check our knowledge based on sound reasoning.

This leads directly and logically to the question of the paroxysmal tachycardias themselves. These are of three types: auricular, auriculoventricular or nodal, both of which are supraventricular in their general classification, and ventricular paroxysmal tachycardias.

From the therapeutic point of view it is important to differentiate these tachycardias. That is not always a simple problem. Theoretically the auricular paroxysmal tachycardias should be recognizable by simple clinical means, because they have certain characteristics, namely, that during an attack successive counts of the heart rate are always uniform. There is no variation. In other words, if the heart rate is 190 and is counted again ten minutes later it will still be 190. Secondly, auricular paroxysmal tachycardia is perfectly rhythmic. Of course, the rate is pretty high, and clinically it is not easy to determine minor variations in rhythm, but electrocardiographically it measures out as perfectly rhythmic. Its recognition is of therapeutic importance because we have means by which it can generally be controlled almost immediately. These include the various factors by which vagal stimulation is brought about: pressure on the eyeballs, the promotion of the carotid sinus reflex by pressure in the neck over one or the other of the two carotid sinuses, the induction of nausea or vomiting by the administration of emetics such as ipecac or apomorphine, or even the stimulation of the vagus by the administration of morphine.

The patient frequently learns tricks of posture that permit him to check his own attacks. He may hold his breath and strain with his glottis closed. He may do a variety of other peculiar stunts which he has learned check his paroxysms, but failing response to any of these the administration of acetyl-beta-methyl-choline, known to the trade as mecholyl, in the form of its hydrochloride, subcutaneously commonly checks a paroxysmal auricular tachycardia almost instantaneously or within a comparatively few minutes at the outside. The dose ranges from 5 or 10 mg. up to 60 or 70 mg., and I have recently seen an example in which the administering physician had rather more courage than I probably would have had myself and administered a single dose of 80 mg. One should always be prepared immediately to check the side actions of acetyl-beta-methyl-choline. They are often quite pronounced. They consist of nausea, vomiting, flushing of the blush area particularly, profuse sweating and often diarrhea. They can be checked at once by the prompt administration of atropine, which is an antagonist,  $\frac{1}{100}$  grain subcutaneously. If the initial dose is 10 mg. and the paroxysmal tachycardia is not checked, one may wait from twenty to thirty minutes and then give a larger dose. I believe it is better to wait than it is to administer small fractions at shorter intervals, though one may proceed by the addition of small fractions.

I know of no satisfactory means of controlling nodal paroxysmal tachycardia. Vagal stimulation is not trustworthy. Mecholyl does not seem to have any particular effect on it. Quinidine may control it but is not as effective in my experience as it is in ventricular paroxysmal tachycardia. Occasionally it would seem as though digitalization checked nodal types of paroxysmal tachycardia. This may be carried out by the usual methods, by oral administration or by intravenous injection in order to bring about a rapid digitalization. I have not had satisfactory results in the control of this form of disturbed cardiac mechanism.

The last of the rhythmic tachycardias is auricular flutter. This condition can be recognized at times clinically and is for the most part readily controllable. There is a high heart rate, usually with essentially rhythmic beating of the heart, the rate however not being excessive. It rarely is above 150 per minute. Above that it is usually paroxysmal tachycardia you are dealing with. It is difficult to differentiate clinically because its features are essentially like an excessive degree of sinus tachycardia. The electrocardiogram solves your problem and permits you to recognize the condition easily. Flutter can be controlled best by overdigitalization or at least maximal digitalization. The administration of digitalis up to or just beyond the point of minor intoxication commonly throws such a patient into a state of auricular fibrillation and then if digitalis is withdrawn the fibrillation is usually replaced by the resumption of a sinus rhythm. Occasionally this does not happen and the patient goes back to flutter. When this is the case, although it introduces an element of hazard, it is sometimes necessary after the termination of digitalization, while the patient is still in the state of fibrillation, cautiously to administer quinidine. Quinidine itself will control a certain proportion of patients with flutter. It must be administered in adequate doses.

Auricular fibrillation is a true arrhythmia, easily recognized clinically, occurring in many organic cardiac diseases, and sometimes without organic cardiac disease of demonstrable nature. The first question we should ask is: Are we justified in checking an auricular fibrillation?

There are two schools of thought on that problem. If the fibrillation is not associated with significant organic heart damage, then one may be justified in terminating it. The best example of this is seen in the patient who has had thyrotoxicosis, who has undergone adequate treatment for it including probably a subtotal thyroidectomy, yet who continues to manifest auricular fibrillation. Here we are often successful in checking the fibrillation lastingly. In general, however, paroxysmal auricular fibrillation, while it may be checked in the majority of cases by the adequate administration of quinidine, usually reappears either on the withdrawal of quinidine or on the reduction of the dose to what is considered safe as a maintenance dose.

In the presence of severe organic heart disease, the commonest form in which we see it being the rheumatic type with mitral stenosis, quinidine is of doubtful value. It is very questionable whether we gain anything by throwing such a patient back into sinus rhythm. For my own part I do not favor its use. I think we can generally control the manifestations of congestive failure more efficiently in such cases by the adequate use of digitalis and allied therapy while the auricles are fibrillating than we can if the heart is reverted to a sinus rhythm. Furthermore, not over about 10 or at most 15 per cent of such patients can be kept in sinus rhythm for any significant length of time.

I should like to speak of one other thing, and that is heart block. Ordinarily mild degrees of heart block, such as simple prolongation of the conduction time, or occasional dropped beats, seldom require any intervention except the elimination of the factor that is responsible, which commonly is digitalis in overdoses. Its withdrawal is followed by a return to sinus rhythm. Where, however, we have the Adams-Stokes syndrome, then we are faced with a crisis which must be met

Here there are two procedures. The first is the administration of epinephrine or ephedrine. At times this immediately increases the heart rate and checks the Adams-Stokes syndrome.

A second remedy of some value, but which carries with it some danger, is barium chloride. This must be administered with very considerable care and circumspection. A dose of from 20 to 30 mg, perhaps rising to as high as 50 mg, three or four times a day may increase the myocardial irritability sufficiently to prevent the occurrence of the Adams-Stokes syndrome or to check an attack.

There is a danger in the administration of epinephrine in that the Adams-Stokes syndrome may be the only recognizable manifestation of a recent myocardial infarction. I have seen two such cases. They were recognized, of course, and checked by electrocardiographic studies subsequently. But here the administration of epinephrine is risky because of the inherent danger of possibly producing a ventricular fibrillation.

But I am sure that I have already spoken long enough, for I have stolen two minutes that were not assigned to me.

#### PHARMACOLOGIC ASPECTS

DR HARRY GOLD. There is experimental basis for the use of the barbituric acid compounds in the treatment of premature contractions and other forms of arrhythmias or disturbance of rhythm involving hyperexcitability or hyper-rhythmicity of the heart. It has been shown experimentally that the barbituric acid compounds prevent idioventricular rhythms by doses of epinephrine or ephedrine which in the untreated animal will produce these rhythm disturbances.

The explanation of the action of the sedatives may be in part their direct action on the heart and in part those other factors which Dr Eggleston has mentioned.

With regard to quinidine intolerance, there are some interesting observations which indicate that the isomers of quinidine may often fail to produce signs of intolerance in individuals in whom quinidine itself produces signs of intolerance, and so you find individuals who cannot take quinidine but can take quinine. Quinine is the levorotatory isomer. Dawson of Texas has made a detailed examination of the related cinchona alkaloids with regard to the production of hyper sensitivity reactions. He found, for example, one individual in whom one of these compounds produced an asthmatic attack. This person could take a compound of opposite rotation without encountering this reaction.

Dr Eggleston used the term "manifest signs of intoxication" in connection with quinidine doses. I think it might be wise to call attention to the fact that there are important toxic actions of quinidine which perhaps are not "manifest." Of course, in a person in whom impaired hearing, impaired vision and gastrointestinal symptoms appear there is no trouble about the recognition of the symptoms, but these effects do not occur in some and the toxic effects are directly on the heart. These are recognizable in their early stages only by an electrocardiogram, in which there is a prolongation of the QRS time. The normal QRS time is about 0.08 second, and after doses as high as 30 grains or 40 grains of quinidine sulfate the QRS time may rise to as high as 0.12 second. I think it would not be well to allow the drug to exceed that, although a prolongation of that order does not appear to be injurious.

The question of tolerance to quinidine was brought up by Dr Eggleston. I think it is a very important subject. There is the prevailing view that tolerance occurs, but we had an occasion to make a very striking experiment with regard to tolerance in an individual who is subject to frequent paroxysms of auricular fibrillation or flutter, with two, three or four such attacks a day, almost entirely incapacitating him. He was subject to them for years, and he was not relieved by anything that he had taken, even quinidine in the doses that had been used before coming to our clinic. We began to give him quinidine in mounting doses until we reached the dose of 60 grains a day. When we got there, all the attacks disappeared, and at the time the case was reported about two and one-half years had passed, and now I believe about four and one-half years has passed in which this patient has been on 50 to 60 grains every single day, with the exception of the experimental periods when we wanted to see what would happen if we withheld it. In him there has at no time been any indication of a developing tolerance to the drug. Every time we withhold it, within three or four days he again has attacks of auricular fibrillation and flutter, sometimes one and sometimes the other.

DR JANET TRAVELL: Didn't that man have some prolongation of QRS time?

DR GOLD: Yes. This was a very interesting case in another respect. It shows how relatively innocuous quinidine can be if it is used in the right way, even though one uses very large doses. He started with a bundle branch block. He had a QRS time of 0.12 second at the beginning and we raised his QRS time to 0.16 second, but it never went beyond that point. It took about 30 to 40 grains a day to bring it up to 0.16 second. Here is a person with a very badly damaged heart, with a bundle branch block to start with, taking 60 grains daily entirely safely and entirely free from attacks, as a result of such doses as one usually thinks would be dangerous. I think it is a safe procedure if one does it in this way, when one reaches a dose of 30 grains a day, begin to take electrocardiograms frequently to see what the QRS time is doing.

The cumulation of quinidine ceases in a very few days with a fixed daily dosage. By that I mean that, if the patient receives 60 grains of quinidine every day, the intensity of the effect measured by whatever phenomenon you select to measure the intensity—suppose it is the QRS time—will cease to increase after a few days. On the first day there will be some effect, on the second day there will be more effect, the third day still more effect, the fourth day perhaps still more effect and about the fifth day the effect will cease to increase. From now on the intensity of the effect that is reached will remain unchanged even though you continue to give exactly the same dose every day for months and years.

This is important to recognize because it means that once you have obtained a level of effect you do not have to worry much about further accumulation of quinidine which might produce more toxic effects on the heart. If you are measuring the QRS time you may find it lengthen to 0.12, 0.13 and perhaps to 0.14 second on the third day and to 0.15 or 0.16 second, let us say, around the fifth day of the use of a large dose of quinidine, but then it will not rise higher. You might ask whether it can rise higher. In the experiments that we carried out in connection with this matter, we determined that it can rise higher if you give larger doses,

so that there is no doubt about the fact that accumulation of quinidine is a self-limiting process and that accumulation ceases after the first four or five days of a fixed daily dosage.

DR ROBERT F. WATSON: I should like to emphasize a few of the points that Dr Eggleston has brought up. The first one concerns the practical aspects of treating paroxysmal tachycardias, especially if one is outside and cannot obtain an electrocardiogram to establish definitely the type with which one is dealing.

Of course most cardiologists realize the small differences clinically between the two essential types of paroxysmal tachycardia (the ventricular and the supraventricular), the differentiation of which becomes important in the therapy. The physician practicing on the outside does not always know or cannot always tell the difference between the ventricular and the supraventricular types clinically. Certainly in those cases one should not use digitalis if for any reason one suspects that the patient may have ventricular tachycardia. It is one instance in which digitalis is not indicated and may be definitely contraindicated.

In that case certainly the best thing to try would be large doses of sedatives, probably morphine, and the usual methods of vagal stimulation, such as carotid sinus pressure or pressure on the eyeballs. If these simpler methods failed then quinidine would probably be a much safer drug than digitalis, especially if there was a chance of the ectopic rhythm being ventricular in origin.

With regard to acetyl-beta-methyl-choline (or mechohyl), a drug which has recently been used in the treatment of paroxysmal auricular tachycardia, I might say that it should not be given until the more common methods of stopping the attack have been tried. It is not entirely without some danger and certainly the more common methods of treatment, such as vagal stimulation, sedation and the administration of ipecac, should be tried before one resorts to mechohyl. Mecholyll is used in varying doses, as Dr Eggleston has said. The dose may vary anywhere from 5 to 10 mg. to 50 or 60 mg., and it is certainly wise to start with a small dose. As a rule, the dose is better tolerated by an older person and varies somewhat with weight, that is, a younger person who weighs approximately the same as an older person usually will be more susceptible to the drug than the older person.

Often after injecting the acetyl-beta-methyl-choline, if the attack does not subside rapidly, that is, within two or three minutes, massaging the site of injection will increase the action of the drug and end the attack. If this does not cause reversion to normal rhythm, vagal stimulation by carotid sinus pressure together with the action of the drug may be effective whereas carotid pressure alone previously had not been successful. Before increasing your dose then it is always wise to try massage of the original site and also pressure of the carotid sinus together with the smaller dose.

It is also necessary that one keep atropine at hand when one is using this drug. It is an antagonist and will relieve the symptoms quite rapidly. Usually a fiftieth to a hundredth of a grain is kept ready and is used intravenously if necessary.

In the tachycardias sometimes all the usual methods (in the supraventricular as well as the ventricular types) may be unsuccessful and the patient may be very dangerously ill with cardiac failure. In that case the

one drug which will probably be most useful is quinidine. Quinidine intravenously occasionally has to be used in very rare cases. The dose varies from 0.2 to 0.4 Gm. given very, very slowly, and just as soon as the rhythm reverts to normal the administration is discontinued.

I should like to ask Dr. Gold about the patient he mentioned with the bundle branch block and the frequent attacks of auricular fibrillation and flutter. Apparently this patient had quite definite heart disease and frequent attacks which bothered him considerably. I wonder if it would not be better in the usual case (not questioning the fact that he obtained very good results with this one case) to digitalize such an individual rather than pushing quinidine to such a degree?

DR. GOLD: The average case of paroxysmal auricular fibrillation cannot be controlled by digitalization. I do not believe that I know any cases of paroxysmal auricular fibrillation or flutter in which we have been able by thorough digitalization, up to as much as they can endure, to abolish their paroxysms.

DR. WATSON: I did not mean to prevent it, I meant to control it when they have an attack.

DR. GOLD: The answer to that from our experience is that if we digitalize the patient in the ordinary way, when a paroxysm of fibrillation develops the heart rate is still rapid and that brings us to an important question: How does digitalis slow heart rate? Let us consider a patient with paroxysmal attacks of auricular fibrillation. When he is not digitalized he comes in with a heart rate of 140. We put him on average doses of digitalis of the order of  $4\frac{1}{2}$  grains or 6 grains daily, and he continues on that way for months. Then two months later he comes in with another attack. He has been on digitalis throughout this period but his rate is still 140.

DR. WATSON: Do you digitalize fully?

DR. GOLD: The problem of the individual who has an attack of paroxysmal fibrillation once in two months is very difficult. It isn't often feasible to have him fully digitalized throughout this time in anticipation of the rare attack.

DR. WATSON: I understood that this patient had it much more frequently.

DR. GOLD: This patient was thoroughly digitalized until he was walking about week on end in a state of nausea and had as many attacks as he had before the quinidine was given. He had been run through every conceivable kind of management, so that for this one digitalis was out of the question. But our experience with these cases by and large is that it is practically impossible to insure a slow ventricular rate when a paroxysm comes, by continued digitalization. I think the reason for that is that the slowing of the ventricular rate by the ordinary doses of digitalis in the ordinary cases of heart failure with auricular fibrillation is not due to the same mechanism by which we are trying to slow it in most cases of paroxysmal auricular fibrillation. We do not have the time now to analyze the situation, but I believe that the slowing in the case of the individual with heart failure and auricular fibrillation is due chiefly to an improvement of the heart failure and that that takes much less digitalis than is required to slow the rate by the direct action on the conducting mechanism, which is the necessary mechanism when heart failure is not present.

DR. CATTELL: Do you care to comment on that, Dr. Eggleston?

DR. EGGLESTON: I think it ought to be emphasized that a large percentage of these patients who are subject to paroxysmal flutter or paroxysmal auricular fibrillation are within the older age group where there are degenerative changes of vascular origin, and the question has arisen in my own mind at least whether we were justified at all in attempting to control these paroxysms unless the paroxysm was a source of genuine discomfort or threat to the patient's welfare. In general, it has been my practice not to control them, not to attempt to prevent the paroxysms.

This is a very interesting case that Dr. Gold speaks of, but within my personal experience I have not been very successful in accomplishing such dramatic results from even maximum tolerated doses of quinidine. I think this is one of the more unusual responses. Is that your experience?

DR. GOLD: We have had several successful cases. In most instances the intervals between attacks are too long to apply this treatment satisfactorily.

DR. HENRY B. RICHARDSON: This morning there has been brought out the clinical distinction of various types of paroxysmal tachycardia. I should like to cite a case that occurred in my experience. A patient had a very violent pulsation in the veins of the neck, and that was improved by his remaining in bed. I believe there is a coincidence in time between the auricular and succeeding ventricular contractions. That appears then to be a point in the differential diagnosis. I should like to know to what extent that is useful.

DR. EGGLESTON: Theoretically that should raise the suggestion that it was a nodal tachycardia with retrograde auricular conduction so that ventricular and auricular systoles approximately coincided. The easy direction for the wave to flow under those circumstances would be back into the veins.

DR. RICHARDSON: Patients with paroxysmal tachycardia of auricular origin sometimes have an increase in the PR interval. If the rate is too rapid the ventricular contraction then coincides with the next auricular contraction, producing a large venous wave in the neck.

DR. ADE T. MILHORAT: Might I say a few more words about mechohyl? It is well to remember that the patient should be in the reclining position because, owing to a fall in blood pressure, the patient might otherwise faint. Secondly, as has been emphasized, massaging the site of injection can induce further action of the drug, therefore the site of injection should be massaged shortly after the drug has been administered. The drug should never be given intravenously.

There are two important conditions in which the drug is contraindicated. These are asthma and hyperthyroidism. Patients susceptible to asthma will have a severe attack if mechohyl is administered, and it should be given cautiously in hyperthyroidism because Nahum and Hoff have observed the development of auricular fibrillation in four patients who previously had normal cardiac rhythm.

We observed the development of auricular fibrillation in this clinic in a patient with myasthenia gravis who was given large amounts of prostigmine. Many of the effects of prostigmine are similar to those of mechohyl. Furthermore, there appears to be an antagonism between quinidine and mechohyl. Patients receiving quinidine are likely not to respond to mechohyl. The mechanism of this antagonism in the cardiac muscle appears to be similar to that observed in the

striated muscles. There is an antagonism between quinine derivatives and drugs which have effects similar to those of vagal stimulation.

DR CATTELL. Why should mechohyl cause fibrillation?

DR MILHORAT. I do not know. I discussed that situation with Dr Starr. He believes that any suitable myocardium might develop auricular fibrillation. Why this should occur he does not know, nor do I.

DR EGGLESTON. I think it should be emphasized that mechohyl should be the last resort and should not be employed in any of these cases until all the usual methods of controlling paroxysmal tachycardia of auricular origin have been tried faithfully.

I find that a large percentage of physicians do not know anything about the carotid sinus. They do not seem to know even where it is and it is pretty much of an accident when they try so-called vagal stimulation whether they approach anywhere near to the carotid sinus or not, but if one can locate by palpation as well as anatomic relations the approximate region of the carotid sinus, pressure on it is very frequently effective.

DR GOLD. I think it is fair to say that no patient has ever had his paroxysmal tachycardia relieved by mechohyl without becoming pretty sick in the process. I think there is an explanation of the fact that mechohyl may cause fibrillation of the auricles. Vagal stimulation shortens the refractive time of the auricle. It is possible that in part the digitalis action in auricular flutter is due to that mechanism, namely, shortening of the refractory time, that may be why a circus movement is set up in the auricle when there is none present. That is why occasionally, in the case of auricular flutter, fibrillation will be produced by mechohyl. After that a regular sinus rhythm is established in much the same way as the way in which digitalis does it. I have often wondered whether in cases of resistant auricular flutter, in which full digitalization is ineffectual, a small dose of mechohyl after the digitalis might not perhaps revert a certain number of them. I refer to those in which digitalis alone appears to be incapable of converting the flutter into fibrillation. I think it would be well worth while trying that out some time.

STUDENT. How often is barium chloride effective in controlling severe heart block?

DR GOLD. It depends on the kind of heart block. I thought of a question in connection with the remarks that Dr Eggleston made about heart block. There are two kinds that cause the Adams-Stokes syndrome. One is the auriculoventricular block in which the heart goes from a regular sinus rhythm to complete block let us say from 80 to 40 a minute, and in that process the patients sometimes faint. The second type is one in which they have a heart block to start with, an idioventricular rhythm which is about 40 a minute, and suddenly it goes down to 10 a minute, they faint in that process. The latter is an anomaly of rhythmicity. Barium chloride is useful in this type. The former is an anomaly of conduction. Occasionally digitalis is helpful here. In the kind in which impaired conduction is the problem, what digitalis does is to produce a persistent auriculoventricular block, and the fainting ceases. They get along pretty well with the constant heart rate of 40 in such cases. I wonder whether Dr Eggleston would comment on this matter.

DR ECCLESTON. I did not think there was time to differentiate between the two conditions. You are quite right, and you have covered the problem. It should be

borne in mind that a complete heart block is consistent with long years of life. Dr Niles and I together have seen a patient who has had a complete heart block from known and proved electrocardiographic signs back in the days when Dr Walter James introduced the first electrocardiograph in this country in the Presbyterian Hospital. How long ago is that Dr Du Bois?

DR EUGENE F DU BOIS. About 1910.

DR EGGLESTON. Twenty-eight years, and he took records on her, and I have seen those original records, and she had a total block then. I saw her within two years, and she is still very well. Her heart rate is just the same.

STUDENT. I would like to ask Dr Eggleston how he finds the carotid sinus and identifies it.

DR EGGLESTON. It lies at the bifurcation of the carotid artery, usually approximately opposite the upper border of the larynx, and I think by gentle manipulation with the fingers, with the neck relaxed, one can make that area out with reasonable certainty. But instead of pressing with a single finger, in order to be on the safe side I have made it a practice of pressing with three fingers, so I would include the carotid sinus without much risk of missing it. At times, of course, you can feel a bulge, but in my experience that is not always possible. I know of no other way of locating it.

The session adjourned at 1:05 p. m.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS  
HOWARD A. CARTER, Secretary

### BURDICK AIR-COOLED QUARTZ LAMP (PROFESSIONAL SPECIAL) CATALOGUE NO. QA-450 ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

The Burdick Air-Cooled Quartz Lamp, Catalogue No. QA-450, is a professional type ultraviolet lamp. It is self starting without tilting and builds up to operating efficiency in approximately three minutes. It operates on 25 or 60 cycle alternating current only. The base is mounted on four 3 inch hard rubber casters. Immediately above the base is the control unit containing the transformer, relay and other electrical parts for starting and operating the burner. Starting switch and ammeter are mounted on top of the control unit. The ammeter is designed to indicate when the burner is built up and ready for use. The unit is finished in ivory and brown with chrome trimmings.

Burdick  
Air Cooled  
Quartz Lamp

A hot cathode mercury quartz lamp of the H Uviarc type is the source of energy. The burner is mounted in an especially designed aluminum reflector which concentrates the radiation to an area 6 feet long by 22 inches wide. The hood is of double walled construction with provision for ventilation and shutters. The reflector may be adjusted so as to direct the radiation vertically downward, horizontally or at an angle with shutters open or partially closed to limit the area of radiation. The lamp is adjustable from a height of approximately 45 inches to 75 inches, the swivel cross arm having an extension of approximately 15 inches.

The firm claims that the lamp will produce ample ultraviolet radiation at a distance of 30 inches from the burner to the patient to produce a first degree erythema (mild reddening) on the average patient after an exposure of thirty seconds.

The firm submitted data concerning the radiation characteristics of the Burdick QA-450 Lamp as determined by a qualified

physicist. A chart shows the spectral distribution and intensity in microwatts per square centimeter.

The unit was investigated clinically for the Council by a qualified physician and was reported to give satisfactory service.

Spectral energy distribution

In view of the foregoing report, the Council on Physical Therapy voted to include the Burdick Professional Quartz Mercury Ultraviolet Lamp Catalogue No. QA 450 in its list of accepted devices.

#### AIRGARD AIR FILTER, MODEL 50, ACCEPTABLE

Manufacturer: Airgard Manufacturing Company, 609 North La Salle Street, Chicago.

The Airgard Air Filter, Model 50, is designed to remove pollen, dust or other solid particles from incoming air for the relief of hay fever or other allergic diseases. It consists of a rectangular metal cabinet (28 inches wide by 12 inches high by 14½ inches deep) with a grilled outlet in front and hooded intake in the rear. The cabinet is lined with a sound deadening material. Operating parts include a specially built motor with sirocco fan constructed on a removable chassis which is mounted on rubber to overcome vibration. It requires a power input of about 65 watts an hour on 110 volt, 60 cycle alternating current.

Removable filter pads or cells are employed. These contain six ply air mat material produced from spruce pulp and treated with a colorless, odorless oil of very low evaporation constant. This matting is encased in cardboard frame in 2 inch convolutions with separators between to increase the area in the small space. Each filter contains approximately 15 square feet of material. Air passes through the filter at a comparatively low velocity.

Incoming air is discharged from the blowers into a plenum chamber, which is acoustically treated and designed to absorb mechanical noises from the operating parts and to muffle outside or street noises.

Airgard Air Filter Model 50

The volume control may be regulated up to 500 cubic feet a minute. The fan speed may also be altered. Recirculation of room air or a combination of room and outside air is possible. With accessory equipment the unit may be converted into an air conditioning plant.

The only therapeutic claim made for the unit is that it will remove 97 per cent of all solid matter carried in the incoming air stream, thus offering relief in allergic diseases caused by inhalation of pollens or dust particles. According to the manufacturer, this efficiency will be maintained throughout the life of the filter cell irrespective of pollen or dust concentrations.

In order to substantiate these claims, the unit was investigated by a competent investigator, who reported as follows:

"After proper installation of the Airgard, 0.5 Gm of giant ragweed (*Ambrosia trifida*) pollen was placed at the inlet of the unit. Several slides were placed in front of the outlet grille and in several positions in the room. The machine was then placed in operation for a period of twenty-four hours. The slides were removed at intervals and examined for the presence

of pollen and dust particles. Using 18 sq. cm as the unit of measure representing the area used in calculating the amount of pollen per cubic yard of air in settling counts, no pollen grains were observed on those slides exposed throughout the room. The slides placed in front of the outlet grille showed only two pollen grains in ten unit areas counted. Considering the massive amount of pollen permitted to enter the intake, which was considerably higher than in entire hay fever seasons, total count, the efficiency in pollen removal is good. Only very fine dust particles of sizes smaller than ragweed pollen, which varies between 12 and 20 microns and probably in the neighborhood of 5 microns and less, were observed on the slides. There were, however, not numerous on the slides exposed before the outlet grille but were more numerous on the slides exposed throughout the room. The latter particles may have been stirred up by air currents although the room had been prepared as dust free as possible."

The variable rheostat regulating the flow of air gives volume varying from 100 to 600 cubic feet of air per minute. The grilles may be adjusted to deflect the air in four directions.

In view of the foregoing report, the Council on Physical Therapy voted to include the Airgard Air Filter, Model 50, in its list of accepted devices.

### Council on Pharmacy and Chemistry

#### PRELIMINARY REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING PRELIMINARY REPORT. PAUL NICHOLAS LEACH, Secretary.

#### COLI-BACTRAGEN (AMERICAN HOSPITAL SUPPLY CORPORATION)

Under the trade name Coli-Bactragen the American Hospital Supply Corporation offered for the Council's consideration a preparation of *Escherichia coli* proposed for use as a prophylactic against peritoneal infections. According to the information supplied by the firm the preparation contains gum tragacanth 15 per cent, alcuronate 0.5 per cent, *Escherichia coli* 2,400 million (treated with 0.5 per cent of formaldehyde solution U.S.P.) in 0.5 per cent salt solution. The firm states that merthiolate in 0.1 per cent of the 1:1,000 solution is used as a preservative. It is administered by injection into the peritoneal cavity before closure of the wound. The recommended dose is 25 cc. of the solution. The claims for the product are based on the work of Dr. Steinberg which was reported in *Surgery, Gynecology and Obstetrics* 57:15 (July) 1933 and in the *American Journal of Clinical Pathology* 4:253 (May) 1936. This is a report of 391 patients under observation in hospitals at Toledo, Ohio. The results substantiate the experiments with dogs. It is claimed that the product acts by mobilizing a large number of leukocytes in the peritoneal cavity and that the gum tragacanth serves to retain them there.

Coller and Ransom (*Ann Surg* 104:636 [Oct] 1936) used the product on seventy-two patients operated on for carcinoma of the rectum. Twelve of these patients died, but of other causes than peritonitis. These authors state that they have used the intraperitoneal injection of some form of Bactragen about 300 times without harmful effect and conclude, "Bactragen (Steinberg) has a place in protecting against infection if gross contamination occurs." It is unfortunate that a control group of patients without the use of Bactragen is not reported on by these authors, although it may be assumed that previous operations served as a basis of comparison.

Horsley (*Arch Surg* 36:190 [Feb] 1938) in a general article on peritonitis devotes two or three pages to a description of the use of Coli-Bactragen (Steinberg) with apparent approval but gives no original data as to the results of his use of the product, in a subsequent publication (*Am J Surg* 40:34 [April] 1938) he again stresses the value of Coli-Bactragen on the grounds of personal experience. In a personal communication which was submitted to the Council, Horsley states:

I have used the Coli-Bactragen rather extensively and while of course it is not a panacea for the prevention of peritonitis it is certainly a very great help. I have had this demonstrated in a number of instances.

Commendatory letters have been received from other surgeons.

The available material offers favorable evidence for the usefulness of Coli-Bactragen as a prophylactic against peritonitis in surgical cases in which the danger of peritonitis appears to be imminent or in the presence of gross contamination occurring at the operation or shortly before. Although Steinberg has reported an adequate number of cases in which the product has been used, the Council feels that more published data from independent sources on the use of the product in human cases are necessary. The label, package and package enclosure are satisfactory except that for greater clarity the sentence 'A period of one and one-half or two minutes should elapse before the material is completely evacuated into the syringe' might be changed to "Since the material is gummy, a period of one and one-half to two minutes should elapse while it is being drawn slowly into the syringe."

The following statement on the label is noted. Effective in 3 hours—Lasts for 3 days. The evidence submitted indicates that this phrase is approximately true but it does not appear to have a legitimate place on the label. The Council would not object to the phrase on a package folder or collateral advertising "May be expected to be effective in about three hours and to continue so for about three days." The statement on the label should be deleted.

The Council has not considered the acceptability of the name 'Coli-Bactragen'. It would not appear, however, to be objectionable provided the firm can establish its right to the use of a coined name for the product. The Council postponed consideration of Coli-Bactragen until further corroborative published evidence becomes available, and authorized publication of the foregoing preliminary report.

## REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS  
PAUL NICHOLAS LEECH Secretary

### ALB-ARGENTUM NOT ACCEPTABLE FOR N N R

Under the name "Alb Argentum" the Alb Argentum Laboratories, Inc. of Boston presented for the Council's consideration a preparation stated to be a compound of silver iodide with a soluble, hydrolyzed gelatin base containing from 18 to 22 per cent of silver iodide in colloidal combination and corresponding to from 83 to 101 per cent of metallic silver. It is said to be prepared by treating hydrolyzed gelatin with silver nitrate to form silver gelatose, which is then treated with the combining equivalent of potassium iodide, filtered and evaporated to dryness in vacuo. The finished product is stated to contain from 0.1 to 0.5 per cent excess of combined potassium iodide over that required to effect the formation of silver iodide. The firm claims that it is nonirritating to mucous membranes, is practically nonstaining and will not coagulate albumin. The firm also claims that *in vitro* laboratory tests indicate that it is as effective as like concentrations of phenol against *Staphylococcus aureus* and the *gonococcus*. The Council questioned whether this claim meant that the preparation has several merits not found in any other colloidal silver iodide, chief among them being the five enumerated.

The sale of the product is promoted through detailing physicians by personal call and direct mail. The manufacturer did not submit any special bibliography. Sollmann in his *Manual of Pharmacology* states:

*Silver Iodide*—Freshly precipitated silver iodide was recommended by Siter and Uhle 1905 but has not come into general use. Thum 1915 gives a formula for concentrated solution of silver iodide. Colloid silver iodide has been used intravenously similarly to collargol producing leukocytosis etc. (von Voigt and Coriath 1919). A colloidal silver iodide preparation is marketed as Neo-Silver, a colloidal silver chloride as Iunosal.

The Council considered the name Alb Argentum and pointed out that Alb-Argentum is a proprietary name for a mixture of silver iodide with a gelatin base which yields a colloidal solution. Since apparently there is nothing novel in such a preparation the use of a proprietary name is not acceptable. The firm was informed that the Council would not be adverse to the name Silver Iodide Compound or Colloidal Silver Iodide Compound.

The firm was informed that acceptable critical evidence, both experimental and clinical, of the efficacy and nonirritating quality of this particular colloidal silver iodide preparation must be submitted before the product could receive favorable consideration.

After the firm had considered the Council's report it wrote that it could not meet the stipulation that the name be changed. The firm offered no comment on the other objections enumerated in the Council's report but asked simply that it be permitted to withdraw its request for acceptance. In view of the firm's failure to make the product acceptable it is the duty of the Council to inform the medical profession concerning it. The Council therefore declared Alb-Argentum unacceptable for New and Nonofficial Remedies because it is marketed under a coined proprietary name with claims which are not based on acceptable clinical and experimental evidence.

### PULVOIDS SULFANILAMIDE AND SODIUM BICARBONATE (THE DRUG PRODUCTS CO., INC.) NOT ACCEPTABLE FOR N N R

The Drug Products Company's brand of sulfanilamide has been accepted by the Council. When the firm presented this product it also presented a dosage form under the name of Sulfanilamide-Sodium. The firm's attention was called to the fact that 'Sulfanilamide-Sodium' is an erroneous name because the product is apparently not sulfanilamide sodium but a mixture of sulfanilamide and sodium bicarbonate. The firm then changed the name to "Pulvoids Sulfanilamide and Sodium Bicarbonate." It had also been pointed out to the firm that there appears to be no need of prescribing sodium bicarbonate and sulfanilamide in fixed proportions. The purpose of the sodium bicarbonate is to combat acidosis, which will vary in different individuals. It is so easy for physicians to prescribe sodium bicarbonate concurrently as indicated that the combination represented by the product would appear to offer no advantage except as a sales point under the heading "convenience to the physician." The promotion of such a fixed dosage form is likely to encourage lack of discrimination in prescribing these two drugs in proper amounts. In view of this the firm was informed that the Council could not accept this unnecessary and possibly dangerous dosage form. Despite the Council's statement the firm announced its intention of continuing the marketing of this product.

The Council, therefore, declared Pulvoids Sulfanilamide and Sodium Bicarbonate (The Drug Products Co., Inc.) unacceptable for inclusion in New and Nonofficial Remedies because it is a superfluous and possibly dangerous mixture in fixed proportion of well known drugs which had better be administered separately when indicated.

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLE HAS BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

### ANTIPNEUMOCOCCIC SERUM, TYPE I (See New and Nonofficial Remedies 1938, p. 397)

The Gilliland Laboratories, Inc., Marietta, Pa.

*Antipneumococcic Serum Refined and Concentrated Type I*—Prepared by immunizing horses with intravenous injections of the virulent and avirulent cultures of type I and type II pneumococci. Trial bleedings are made at frequent intervals and when the serum has reached a sufficient degree of potency for type I pneumococci the horses are bled repeatedly and the serum is refined and concentrated by the method of Lloyd D. Felton (*J. Infect. Dis.* December 1928, p. 543). The concentrated product contains type II pneumococcus antibodies but not in therapeutically important amounts. After concentration sterility tests are carried out in the manner prescribed by the National Institute of Health and safety tests are carried out by injection into white mice and guinea pigs. The potency of the product is expressed in terms of the unit described by Felton (*Boston M. & S. J.* May 15, 1924, p. 819; *J. Infect. Dis.* September 1925, p. 199; October 1925, p. 309), the unit being one three hundredth cc. of the control serum (P-11) distributed by the National Institute of Health. Marketed in packages of one syringe containing 10,000 units and in packages of one syringe containing 20,000 units each accompanied by a vial of dilute serum (1:10) for the sensitivity test.

## PRESIDENT'S MESSAGE ON THE NATIONAL HEALTH PROGRAM

Elsewhere in this issue<sup>1</sup> appears the complete text of the President's message with which he sent the report of the Interdepartmental Committee to Coordinate Health and Welfare Activities to the Congress of the United States.

The President's message calls attention to the fact that this report is the outgrowth of the National Health Conference which was held in Washington in July and of conferences by the Interdepartmental Committee with special committees representing various organizations in the medical and the health fields. The President points out that he has been particularly concerned by evidence of inequalities that exist among the states as to personnel and facilities for health services and by equally serious inequalities of resources and medical facilities and services in different sections and among different economic groups. "The objective of a National Health Program," he says, "is to make available in all parts of our country and for all groups of our people the scientific knowledge and skill at our command to prevent and cure for sickness and disability, to safeguard mothers, infants and children, and to offset through social insurance the loss of earnings among workers who are temporarily or permanently disabled." There is no proposal for any great expansion of federal health services. The aim is instead a flexible program to be worked out and administered by states and localities with the assistance of federal money.

The President recognizes the increased length of life and improvement of average levels of health and wealth of our people but he is disturbed by the fact that numbers of individuals are still without the benefits which have come to the vast majority. He has therefore recommended the report of the Interdepartmental Committee for careful study by the Congress.

## THE PURIFICATION OF TUBERCULIN

Eight years after the discovery of the tubercle bacillus in 1882, Koch introduced old tuberculin. A tremendous amount of experimental work has since been carried out in an attempt to elucidate the nature of the active principle. Because of the importance of this problem the Committee on Medical Research of the National Tuberculosis Association selected it for thorough investigation years ago. A decade of research by Dr. Florence B. Seibert and her associates has resulted in valuable contributions to our knowledge of the nature of the substance and of its action. The active principle is protein in nature, when tubercle bacilli are cultivated in a synthetic medium, the development of tuberculin activity coincides with the formation of protein. The chemical changes that occur during growth were studied and this active principle was isolated, now known as the purified protein derivative, a product extensively used as a standard substance for the tuberculin test.

Recent reports<sup>1</sup> describe the use of the most modern research tools in an intensive study of substances prepared from tuberculin medium filtrates. The molecular uniformity of the various fractions isolated was determined by means of the Svedberg ultracentrifuge as well as by electrophoresis. Throughout the study of the various preparations the relationship between tuberculin potency and antigenicity on the one hand and molecular size and shape and electrochemical properties on the other was noted. The ultimate object was to prepare homogeneous fractions having certain definite chemical and immunologic properties. By chemical means a homogeneous protein fraction was obtained from human tuberculin which possessed a molecular weight of approximately 32,000 and which contained only 2 per cent polysaccharide. This substance possessed complete antigenicity both in the production of antibodies and in the elicitation of serum and cutaneous reactions.

Further investigation showed that the nonantigenic purified protein derivative, which was thought to be the smallest potent tuberculin molecule, was not homogeneous in sedimentation and that it contained 22 per cent nucleic acid. Electrophoretic studies also indicated the presence of polysaccharide. By fractional precipitation with hydrochloric and trichloroacetic acids and subsequent electro dialysis, a protein fraction was isolated which possessed a molecular weight of about 16,000. This is approximately the same molecular weight as that found for the molecules in the original medium that are antigenic. It is thought that the loss of antigenicity of the substance isolated is at least partly due to a distortion or change of configuration of its molecular structure. A study of this structure indi-

<sup>1</sup> Seibert, Florence B., Pedersen, Kai O. and Tiselius, Arne. Molecular Weight, Electrochemical and Biological Properties of Tuberculin Protein and Polysaccharide Molecules. *Am. Rev. Tuberc.* 38: 399 (Oct.) 1938. The Purification of Tuberculin, editorial and p. 53.

cated that it was not spherical but rather quite asymmetrical and probably considerably stretched. The present practical use of the purified protein derivative as a standard is not affected by the fact that it is not entirely homogeneous, indeed, the opinion has been expressed - that the purified protein derivative of tuberculin is the best reagent so far produced for diagnostic tests in man. Because of the stability and constancy of the purified protein derivative it is invaluable as an agent for the Mantoux test.

While new ideas are of prime importance in motivating investigation, new experimental methods give fresh impetus to research work and alert investigators are quick to take advantage of them. No better example could be cited than the use of the ultracentrifuge and the electrophoresis apparatus as aids in the purification of tuberculin. In little more than a decade since its invention the ultracentrifuge is being used to obtain fundamental data on a substance which promises to be of great importance to the public welfare.

#### MENTAL DISORDERS IN URBAN AREAS

In a recent investigation of the genesis of mental disorders, Faris and Dunham<sup>1</sup> made a record of the geographic distribution of mental disorders as based on their incidence in different socio-economic areas of one large city (Chicago) and one smaller city (Providence, R. I.). Previous sociologic studies have indicated that Chicago may be divided into more or less distinct concentric zones consisting of a central business district, occupied largely by stores, business offices and so on, then a transition zone, characterized by expanding industries, high land values and deteriorating residential buildings with so-called slums, a third zone consisting largely of working men's homes and intermediate in many respects between the slum areas and the residential areas, and two outer zones composed principally of apartment houses and commuter homes and inhabited largely by upper middle class families, many of them owning their homes. Since all patients with mental disorder in Chicago, who are cared for in public institutions are brought first to the Cook County Psychopathic Hospital, it was not difficult to allocate all state institutional patients to their zones of residence. The total number of cases for each zone (more detailed divisions were actually employed) was divided by the adult population of that community in order to obtain the frequency rates. The resultant rates ranged from a low of 110 cases of mental disease per hundred thousand of adult population in a high-class residential area to a high of 1,757 in the central business district. The distribution, in fact, in Chicago showed a definite pattern, the highest rates being clustered about the

center of the city with progressive lowering as the distance from the center increased, with the exception of certain known deteriorated regions near the periphery. The investigators then plotted the distribution patterns of certain pathologic types of insanity, namely schizophrenia and its clinical varieties, manic-depressive psychosis, alcoholism and drug addiction, dementia paralytica in vice areas and the psychoses of old age. For schizophrenia as a whole, the configuration of distribution was strikingly similar to that of all types of mental disorder combined, although there were certain wide differences in the patterns of certain clinical types. The manic-depressive psychoses, however, were unlike schizophrenia in almost every respect of distribution, the former failing to show a typical pattern or any definite concentration in the more central, disorganized and poverty-stricken areas in the city. In fact there was a manifest tendency, although not clearly defined, for the manic-depressive to come from a higher cultural and economic level than the schizophrenic cases. The rates for alcoholic psychoses and drug addiction were also at their highest in and near the center of the city in the so-called zone of transition, and dementia paralytica had its greatest frequency in the proximity of houses of prostitution. The psychoses of old age, on the other hand, tended to concentrate in the central slum and Negro communities, but the rates did not always appear to represent a function of the distance traveled from the center of the city, as was the case with schizophrenia and mental disorders as a whole. In general, with allowances for local differences, the observations in Providence were similar to those in Chicago.

Following these factual investigations the authors presented a hypothesis to explain at least some of the observations. After discussing other possibilities they suggest that the nature of social life and conditions in certain areas of the city are in some way the cause of high rates of mental disorder. Especially for the schizophrenic group they believe that the lack of adequate social contacts in the disorganized sections of the city, from which most cases of mental disorder arise, produces a sense of isolation in the individual, which moves him in the role of an outcast and has a tremendous effect on the development of the personality. Lack of sufficient self confidence and the consciousness that others do not desire one's company may act as a serious barrier to intimate social relations and may therefore be a significant factor in accounting for the high rates of schizophrenia in certain parts of the city. In further support of this contention are the observations that a "spoiled childhood" is found in the background of more than 50 per cent of persons with schizophrenia and that persons living in communities which are populated not primarily by people of their own nationality or race are more liable to certain forms of mental disorder than when they are living in other communities where the majority of the people are like

<sup>2</sup> Parish H. J. The Modern Outlook on Tuberculin. *Tubercle* 19 (May) 1938.

<sup>1</sup> Faris R. E. L. and Dunham H. W. Mental Disorders in Urban Areas. An Ecological Study of Schizophrenia and Other Psychoses. Chicago University of Chicago Press January 1939.

themselves as to race or nationality. This study shows that urban areas characterized by high rates of social disorganization are also those with high rates of mental disorder. Whatever the validity of the proposed hypothesis to explain this association may prove to be, the facts gathered alone, while they may or may not suggest lines of cleavage that will point the way to a clinical classification, as H. Douglas Singer suggests in the foreword, constitute a contribution of fundamental importance to this difficult subject.

## Current Comment

### INCIDENCE OF TONSILLECTOMY

Glover<sup>1</sup> has recently estimated that 200,000 tonsillectomies are performed annually in England and Wales. After the war, during which there was a lull in the number of tonsillectomies, a rapid rise led to a peak in 1931. In that year Newman strongly urged a more conservative attitude toward this operation. Other similar reports also exerted a definite influence on medical opinion. Since 1935, after a considerable drop, the rate has been rising once more. The operation is more frequent in boys than in girls, the highest age incidence is in the period 5 to 7 years. This high incidence between 5 and 7 is, Glover believes, due to many operations at this age being performed on tonsils for enlargements which are either physiologic—that is, associated with great changes in development and in the oral cavity—or immunologic and in response to the unaccustomed herd infections of the new environment of school or to the sepsis sometimes resulting from the decay of the primary dentition. The geographic distribution in elementary school children revealed no correlation between the rate of incidence and any factor such as overcrowding, poverty, bad housing or climate. Tonsillectomy, furthermore, is not correlated with the general efficiency of the school medical and dental services and in fact defies any explanation other than that of variation of medical opinion on the indications for operation. Large and in some cases drastic reduction in the numbers of operations performed in elementary school children in certain areas have had no unsatisfactory result. Tonsillectomy is at least three times as common in well-to-do classes as in the poor. But in the public schools (corresponding to our private schools) the picked athletes among the boys are tonsillectomized in exactly the same proportions as the other boys in the schools they represent. These facts, together with the undoubted brilliant results of tonsillectomy in individual cases, have led, Glover believes, toward tonsillectomy in many doubtful cases. The operation is too often performed without adequate cause or sufficient regard to the possibility of enlargement being temporary or due to physiologic or immunologic causes. Furthermore, from the English statistics available the mortality from the operation is larger than is generally appreciated. The bare facts of incidence seem to

support the opinion expressed on other grounds by the Schools Epidemic Committee that "it is a little difficult to believe that among the mass of tonsillectomies performed today all subjects for operation are selected with true discrimination, and one cannot avoid the conclusion that there is a tendency for the operation to be performed as a routine prophylactic ritual for no particular reason and with no particular result."

### PRODUCTION OF GONADOTROPIC SUBSTANCE BY PLACENTAL TISSUES

Demonstration by Gey and his colleagues<sup>1</sup> of Johns Hopkins University that test tube cultures of placental cells liberate the gonad stimulating factor resembling "prolan" constitutes the first laboratory confirmation of a currently accepted clinical theory, moreover, their work suggests methods of experimentation presumably applicable to numerous hypothetic or suspected hormones. Most clinicians believe that the placenta produces much if not all of the gonadotropic substance excreted in the urine of pregnancy. Thus far, however, there has been no direct experimental confirmation of this theory. Gey and his colleagues suggested that the postulated placental function might be confirmed by studying the hormonal properties of metabolic products formed by placental cells grown in artificial culture mediums. Two cultures of placental tissues were therefore prepared, one from a three month's placenta obtained by hysterectomy, the other from a hydatidiform mole. Fragments of these tissues were grown in roller tubes,<sup>2</sup> the tubes being rotated at a constant speed of twelve revolutions an hour. The supernatant fluid was changed every three or four days. The culture medium selected for these roller tubes consisted of four parts of human cord serum, four parts of chicken plasma and one part each of beef embryo extract and a balanced salt solution. The production of gonadotropic substance by the placental tissues was tested by performing the Aschheim-Zondek test on 21 day old rats, control tests being made with unexposed culture medium or with the same culture medium after three days' exposure to a culture of normal human muscle fibroblasts. In most of their tests the three day supernatant fluid from one or both of the two placental cultures gave positive Aschheim-Zondek reactions, the control tests being uniformly negative. They conclude from this evidence that "placental cells produce a substance similar to the prolan-like substance found in the urine of pregnant women." The cells responsible for this hormonal activity are presumably the Langhans cells. To their surprise parallel tests with the supernatant fluid bathing cultures of human anterior pituitary cells gave negative assays of the gonad stimulating factor. Gey and his colleagues hope to extend their observations to additional material. Since mole and chorionepithelioma tissues are rarely available they seek cooperation in obtaining a supply of appropriate material.

# ORGANIZATION SECTION

## THE PRESIDENT'S MESSAGE ON THE NATIONAL HEALTH PROGRAM

The text of President Roosevelt's message to Congress January 23 proposing a National Health Program follows

"In my annual message to the Congress I referred to problems of health security. I take occasion now to bring this subject specifically to your attention in transmitting the report and recommendations on National Health prepared by the Inter-Departmental Committee to coordinate health and welfare activities.

"The health of the people is a public concern, ill health is a major cause of suffering, economic loss, and dependency, good health is essential to the security and progress of the nation.

"Health needs were studied by the Committee on Economic Security which I appointed in 1934 and certain basic steps were taken by the Congress in the Social Security Act. It was recognized at that time that a comprehensive health program was required as an essential link to our national defenses against individual and social insecurity. Further study, however, seemed necessary at that time to determine ways and means of providing this protection most effectively.

"In August 1935 after the passage of the Social Security Act, I appointed the Inter-Departmental Committee to Coordinate Health and Welfare Activities. Early in 1938, this committee forwarded to me reports prepared by their technical experts. They had reviewed unmet health needs, pointing to the desirability of a National Health Program, and they submitted the outlines of such a program. These reports were impressive. I therefore suggested that a conference be held to bring the findings before representatives of the general public and the medical, public health, and allied professions.

"More than 200 men and women, representing many walks of life and many parts of our country, came together in Washington last July to consider the technical committee's findings and recommendations and to offer further proposals. There was agreement on two basic points, the existence of serious unmet needs for medical service, and our failure to make full application of the growing powers of medical science to prevent or control disease and disability.

"I have been concerned by the evidence of inequalities that exist among the states as to personnel and facilities for health services. There are equally serious inequali-

ties of resources, medical facilities and services in different sections and among different economic groups. These inequalities create handicaps for the parts of our country and the groups of our people which most sorely need the benefits of modern medical science.

"The objective of a National Health Program is to make available in all parts of our country and for all groups of our people the scientific knowledge and skill at our command to prevent and care for sickness and disability, to safeguard mothers, infants and children, and to offset through social insurance the loss of earnings among workers who are temporarily or permanently disabled.

"The committee does not propose a great expansion of federal health services. It recommends that plans be worked out and administered by states and localities with the assistance of federal grants-in-aid. The aim is a flexible program. The committee points out that while the eventual costs of the proposed program would be considerable, they represent a sound investment which can be expected to wipe out, in the long run, certain costs now borne in the form of relief.

"We have reason to derive great satisfaction from the increase in the average length of life in our country and from the improvement in the average levels of health and well-being. Yet these improvements in the averages are cold comfort to the millions of our people whose security in health and survival is still as limited as was that of the nation as a whole fifty years ago.

"The average level of health or the average cost of sickness has little meaning for those who now must meet personal catastrophes. To know that a stream is four feet deep on the average is of little help to those who drown in the places where it is ten feet deep. The recommendations of the committee offer a program to bridge that stream by reducing the risks of needless suffering and death, and of costs and dependency, that now overwhelm millions of individual families and sap the resources of the nation.

"I recommend the report of the Inter-Departmental Committee for careful study by the Congress. The essence of the program recommended by the committee is federal-state cooperation. Federal legislation necessarily precedes, for it indicates the assistance which may be made available to the states in a cooperative program for the nation's health."

## AMERICAN PUBLIC HEALTH ASSOCIATION AND THE NATIONAL HEALTH PROGRAM

The American Public Health Association on January 9 submitted to the Technical Committee on Medical Care its official judgment about the means by which the principles of the National Health Program may be translated into action.

The recommendations of the American Public Health Association were developed by a committee appointed to confer with Miss Josephine Roche, chairman of the Interdepartmental Committee to Coordinate Health and Welfare Activities. The committee met in Washing-

ton, D. C., Nov. 19, 1938, at the request of Miss Roche. The committee consisted of Abel Wolman, Dr. Eng, president of the American Public Health Association and professor of sanitary engineering at Johns Hopkins University, J. N. Baker, M.D., Montgomery, Ala., Louis I. Dublin, Ph.D., New York, A. T. McCormack, M.D., Louisville, Ky., H. S. Mustard, M.D., New York, J. L. Rice, M.D., New York, F. J. Underwood, M.D., Jackson, Miss., and, ex officio, E. S. Godfrey, Jr., M.D., Albany, N. Y., and Reginald M. Atwater, M.D.,

New York The committee's report has been endorsed and accepted by the American Public Health Association

In his press release January 9 the executive secretary of the American Public Health Association said

These recommendations, we believe, agree in most points substantially with the proposals of the Interdepartmental and Technical Committees on the federal-state relationships embodied in the National Health Program, and we agree that the primary federal function is to give financial and technical aid to the states for carrying out approved programs

Following are the recommendations made by the Association to the Technical Committee

1 It is certainly theoretically desirable that a single state agency should be made administratively responsible for carrying out all the provisions of the National Health Program which may be enacted into law

In recommending that this single agency should be the state department of health, we recognize that the present patterns in most states do not conform to this proposal yet we note evidence that organized medicine and many public welfare officials share our opinion that at least ultimately the state health department should be the responsible agency We believe that there are many affirmative reasons why the state health department is the best agency at the state level for this purpose No agency will be able so readily or effectively as the health department to provide professionally qualified personnel and be so readily or effectively able to maintain high professional standards of medical care

In recommending that the state health department should be the primary integrating and coordinating unit, we recognize that the counsel of qualified advisers from the medical, dental, nursing, hospital and ancillary professions will be requisite, that adequate provisions for technical staffs and administrative expense will have to be made from the outset, and that increased funds for training purposes will be essential for successful performance We have concluded further that, however reluctant medical health officers may be at present to take over these added responsibilities, a study of the alternative choices for such purposes will be determinative This basic recommendation does not preclude a working arrangement in some states with existing machinery outside of the official health department which might function well through another channel, provided that the state health officer retains supervisory control over the broad plans and the general purposes of the funds which the state may receive It is further recommended that in such plans due consideration will be given to the allocation of funds by a state department of health to the various substantial governmental

jurisdictions within a state where population, extent of the special problems or financial need justify

We note that this proposal is in accord with the recommendation of the Interdepartmental Committee that this program should be developed around and be based upon existing preventive health services

2 The committee reaffirms and reemphasizes the official declaration of the American Public Health Association that in the initiation and development of the program, wide latitude should be given to the states in the definition of the population to be served, in the selection of the method of providing medical service and in other important phases of the proposed program We believe that similar latitude should be provided with regard to the method of raising funds in the states to accomplish approved objectives

3 The committee finds itself in agreement with the recommendations in the National Health Program that the fundamental objectives involved here are, first, conservation of health and vitality and second reduction of the role of sickness as a cause of poverty and dependency With this in mind it supports the concept that recommendations 1, 2 and 3 of the Interdepartmental Committee (the expansion of public health and maternal and child health services, the expansion of hospital clinic and other institutional facilities, and the provision of medical care for the medically needy) should have priority in initiation

4 We believe that recent experience demonstrates that the Social Security Act provisions for aid to the states for health work provide a suitable framework for the expansion of preventive health services

5 We submit that it is essential that any state program to be approved for federal aid should contain adequate provisions for the maintenance of high personnel standards and that payment of such federal aid to state agencies should be withheld when it is found that substandard services are being furnished Similar policy should obtain with respect to state aid to local areas within a state The appropriate federal administrative authorities should have power to establish minimum standards through rule and regulation after consultation with competent advisory professional bodies

6 Careful study will be necessary to perfect administrative regulations to cover the details concerned with the provision of medical services, so as to assure a high level of quality We believe that standards of medical practice should not be written into basic law Federal aid should be conditioned on inclusion within the state plans of adequate safeguards for maintaining appropriate standards

7 We believe that the extension and improvement of public health services in general throughout the country require complete integration of health services of the federal government under one cabinet officer, preferably a Secretary of Health

## OFFICIAL NOTES

### ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

#### Program of Meetings to Be Held in Chicago, February 13 and 14

The Thirty-Fifth Annual Congress of the Council on Medical Education and Hospitals of the American Medical Association will be held at the Palmer House, Chicago, February 13 and 14 The Federation of State Medical Boards of the United States will participate in the Congress The program follows

#### MONDAY, FEBRUARY 13, 10 A M

*The Protection of the Public Through the Activities of the Council on Medical Education and Hospitals of the American Medical Association*  
Ray Lyman Wilbur M D, LL D, Chairman Stanford University Calif

*College Education for the Future Doctor*

James B Conant, Ph D President Harvard University Cambridge Mass

*The Organization and Subject Matter of General Education*

Robert Maynard Hutchins LL D President, University of Chicago

*Canadian Experiments in Medical Economics*

T C Routley M D LL D, General Secretary, Canadian Medical Association Toronto Ont

#### MONDAY, FEBRUARY 13, 2 15 P M

*The South as Testing Ground for the Regional Approach to Public Health and Public Welfare*

Howard W Odum LL D Director, Institute for Research in Social Science, University of North Carolina, Chapel Hill

#### SYMPOSIUM ON THE SMALL HOSPITAL

*The Community Hospital*

Barry C Smith General Director The Commonwealth Fund New York

*Organization and Management of the Small Hospital*

Malcolm T MacEachern M D Associate Director, American College of Surgeons Chicago

*Planning for a Small Hospital*

William Henry Walsh M D Consultant Specialist on Hospitals Chicago

*The Construction of the Small Hospital*

Carl A Erikson of the firm of Schmidt, Garden and Erikson Architects Chicago

TUESDAY, FEBRUARY 14, 9 30 A M

*The Program of the National Committee for Mental Hygiene*

Clarence M Hincks M D, General Director National Committee for Mental Hygiene New York

*Fundamentals of Industrial Hygiene*

T Lyle Hazlett M D Professor of Industrial Hygiene, University of Pittsburgh School of Medicine and Medical Director, Westinghouse Electric and Manufacturing Company Pittsburgh

*The Relation of Anesthesiology to Medical Education*

Ralph M Waters M D, Department of Anesthesia, University of Wisconsin Medical School Madison

*Tenure of Members of the Faculty in Schools of Medicine*

Anton J Carlson Ph D Frank P Hixon Distinguished Service Professor of Physiology University of Chicago

TUESDAY, FEBRUARY 14, 12 30 P M

Luncheon meeting, to which all those attending the Congress are invited to attend

Address *What the Undergraduate College Should Give the Future Doctor*

William Mather Lewis, LL D President, Lafayette College, Easton Pa

THE FEDERATION OF STATE MEDICAL BOARDS

MONDAY, FEBRUARY 13, 6 30 P M

FEDERATION DINNER

Address *Recent Impressions of British Medical Education*

Willard C Rappleye M D Dean Columbia University College of Physicians and Surgeons New York

Address H J Lehnhoff M D President The Federation of State Medical Boards Lincoln Neb

Round Table Discussion

TUESDAY, FEBRUARY 14, 9 30 A M

*Does Modern Medical Licensure Procedure Conform to the Accepted Standards of Medical Education?*

A C Furstenberg M D Dean University of Michigan Medical School Ann Arbor

*Examination Results Before Massachusetts State Board of Registration in Medicine*

Edward A Knowlton M D, Holyoke Stephen Rushmore M D Boston

*American Graduates of British Medical Schools*

Harold Rypins M D Secretary New York State Board of Medical Examiners Albany

*Citizenship and Medical Licensure*

J Earl McIntyre M D Secretary Michigan State Board of Registration in Medicine Lansing

*Legal Status of the Intern*

Fred E Clow M D Secretary New Hampshire Board of Registration in Medicine Wolfeboro

TUESDAY, FEBRUARY 14, 2 P M

*Hospital Intern Service in the United States*

Robin C Buerki M D Director of Study, Commission on Graduate Medical Education Chicago

*Looking at Health Insurance Abroad*

J George Crownhart Secretary State Medical Society of Wisconsin Madison

*Trends in the Distribution of Medical Care*

R G Leland, M D Director, Bureau of Medical Economics, American Medical Association Chicago

Executive Session

RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company, entitled "Your Health," began Wednesday October 19 and will run consecutively for thirty-six weeks. The program is broadcast each Wednesday over the blue network of the National Broadcasting Company at 2 p m eastern standard time (1 p m central standard time, 12 noon mountain time, 11 a m Pacific time) <sup>1</sup>

These programs are broadcast on what is known in radio as a sustaining basis, that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

February 1	Preventing Epidemics
February 8	Avoiding Arthritis
February 15	Healthy Hearts

<sup>1</sup> Owing to program conflicts there will be no Chicago broadcast of the network program. Instead a recording of the program will be broadcast over station WENR at 8 p m each Wednesday. This recording will be an identical rebroadcast of the network program broadcast earlier the same day.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

*Changes in Status*—Public hearings will begin Wednesday morning, February 1, at 10 a m, on social security legislation, in the Ways and Means Committee room of the new House Office Building, Washington, D C. S Res 25 has been agreed to by the Senate, authorizing the Senate Select Committee on Government Organization, created by the Seventy-Fifth Congress, to continue and to have authority to perform the duties and exercise the functions contained in the resolution by which the committee was created.

*Bills Introduced*—S Res 31, submitted by Senator Shepard, Texas, proposes to create a Senate Committee on World War Veterans' Legislation, to consist of seventeen Senators. S 259 introduced by Senator McNary, Oregon provides service pensions for persons who served ninety days in foreign service under the jurisdiction of the Quartermaster General, Surgeon General of the United States Army the Secretary of the Navy or the Marine Corps during the Spanish-American War including the Philippine Insurrection and the Chinese Boxer Rebellion. S 168 introduced by Senator Nye, North Dakota, proposes to prohibit the importation of dairy products produced from milk or cream other than from cows either accredited free of bovine tuberculosis or under test for bovine tuberculosis. S 622 introduced by Senator Lodge Massachusetts proposes to authorize an appropriation of \$1 400 000 to build a new veterans hospital and diagnostic center at or near Boston. S 658 introduced by

Senator Capper, Kansas, is entitled a bill to aid in alleviating the loss caused by sickness. This bill, identical with a bill introduced by Senator Capper in the Seventy-Fifth Congress, proposes an annual federal appropriation of \$200 000 000 to induce the states to develop and maintain adequate systems of health insurance. A federal Health Insurance Board is to be created it is proposed, to administer the act. State plans must be submitted to this board and receive its approval. A state plan to be acceptable must provide for cash benefits to be paid employees for loss due to disability and for medical benefits for employees, their dependent spouses, and dependent children and other members of their family who are dependent on them and live in the same household. Employees entitled to medical benefits, it is proposed, will be permitted to choose physicians from among a list of those who have agreed to render services under the health insurance plan. A majority of physicians or dentists, respectively in a given locality who have agreed to furnish medical benefits under the health insurance system may determine the manner in which they are to be paid for their services being permitted to choose from the following methods: (1) a salary system, (2) a per capita system whereunder payment will be based on the number of persons entitled to medical benefits included in the practitioner's list, (3) a fee system whereunder payment will be based on the extent and character of the treatment given and services rendered by the practitioner to persons entitled to medical benefits and (4) any combination or modification of the systems heretofore stipulated. S 655, introduced by

Senator Barkley, Kentucky, and H R 2890, introduced by Representative Bland, Virginia, propose to create in the United States Public Health Service a Division of Water Pollution Control S 799, introduced by Senator Pittman, Nevada, and H R 2760, introduced by Representative McReynolds, Tennessee, propose to extend the facilities of the United States Public Health Service to active officers of the Foreign Service of the United States S 859, introduced by Senator Crawley, Arkansas, proposes to refund to each physician the amount collected from him by the federal government during the period June 1, 1920, to June 30, 1931, for the privilege of prescribing the hot waters from the Hot Springs National Park provided that no more than \$660 shall be refunded to any one physician H R 31, introduced by Representative Cannon Missouri proposes to reenact all public laws granting medical and hospital treatment, domiciliary care, compensation and other benefits to veterans and their dependents that were repealed by the Economy Act of March 20, 1933 H R 2223 introduced by Representative Connery, Massachusetts proposes to recognize the high public service rendered by soldiers who volunteered and served in trench fever experiments in the American Expeditionary Forces H R 2292 introduced by Representative Rankin, Mississippi, proposes to direct the Administrator of Veterans' Affairs to furnish outpatient pneumothorax therapy, insulin and liver extract to veterans requiring such treatment or medication notwithstanding that the disease necessitating the treatment may not be directly or presumptively service connected H R 2320, introduced by Representative Rankin, Mississippi, proposes to provide domiciliary care medical and hospital treatment and burial benefits to persons recognized as veterans of the Spanish-American War including the Boxer Rebellion and the Philippine Insurrection H R 2404 introduced by Representative Sirovich New York proposes to require a surgeon and ship hospital on every steamer of the United States or of any foreign country navigating the ocean and licensed to carry more than twenty-five passengers that leaves or attempts to leave any port of the United States, except steamers between ports of the United States less than 500 miles apart H R 2425, introduced by Representative May, Kentucky, provides that in no event shall any person by reason of wilful misconduct be denied any of the service-connected benefits under veterans' laws, provided such misconduct did not interfere during service with full performance of military or naval duty H R 2646, introduced by Representative Jarman, Alabama, proposes to provide that any veteran shown to have active pulmonary tuberculosis of a compensable degree shall be deemed to be totally disabled for purposes of compensation when hospitalized H R 2650, introduced by Representative Rogers, Massachusetts, proposes to authorize hospital care and treatment for American veterans residing in foreign countries in such manner as the Administrator of Veterans' Affairs shall by regulation prescribe H R 2746, introduced by Representative Pace, Georgia proposes to authorize an appropriation of \$2,500,000 to erect in the southwest section of Georgia a 800 bed veterans' hospital for the accommodation of veterans entitled by law to such facilities H R 2753, introduced by Representative Voorhis, California proposes to amend the Social Security Act so as to extend its benefits to individuals who are physically disabled H R 2877, introduced by Representative Van Zandt, Pennsylvania, proposes to provide that any person who served in the military or naval forces of the United States during a recognized campaign or expedition, and who was honorably separated from such service, shall be granted hospitalization and domiciliary care by the Veterans' Administration subject to the same restrictions and limitations as are now applicable to World War veterans H R 2892, introduced by Representative Izac, California, proposes to provide that retired personnel of the Army, Navy, Marine Corps, and Coast Guard and Fleet Naval and Fleet Marine Corps reservists requiring hospitalization shall be entitled to enter any Army or Navy hospital on their own request, under the same conditions as are now, or which may hereafter be, fixed for the active service H R 2963, introduced by Delegate Dimond Alaska proposes to authorize an appropriation of \$2,500,000 to establish a hospital for the insane of Alaska H R 2974 introduced by Representative

Voorhis, California, proposes to amend the Social Security Act so as to authorize an appropriation of \$7,000,000 annually to assist states, counties, health districts and other political subdivisions of states to provide medical care to nonresident needy persons on the same basis as to resident needy persons. H R 2979, introduced by Representative Van Zandt, Pennsylvania, proposes to authorize an appropriation of \$2,000,000 to construct in the central Pennsylvania area a veterans' hospital and domiciliary facility for the treatment of general medical and surgical disabilities H R 2985, introduced by Representative Green Florida, proposes to authorize an appropriation of \$2,500,000 to construct in Jacksonville, Fla., a marine hospital H R 2986, introduced by Representative Johnson Indiana, proposes to repeal the Economy Act of March 20, 1933 H R 2988, introduced by Representative Schwert, New York, proposes to provide that in the discretion of the Administrator of Veterans' Affairs, hospital care, including medical treatment may be furnished to veterans of the World War temporarily sojourning or residing abroad, for disabilities due to war service in the armed forces of the United States

## STATE MEDICAL LEGISLATION

### Arizona

*Bills Introduced*—H 3 proposes to require applicants for licenses to marry to present a physician's certificate that they are free from 'infectious contagious and venereal disease' A physician's certificate must be based on physical examination, tuberculin tests and laboratory reports of microscopic examination or the complement fixation test for gonorrhea, or both, and the blood Wassermann test or Kahn test for syphilis, or both. H 7 proposes to exempt from the sales tax the proceeds of sales of 'medicines purchased through a physician's prescription'

### California

*Bills Introduced*—S 130 and A 493 propose to require a physician or other person attending a pregnant woman to obtain or cause to be obtained a blood specimen at or within ten days after his first professional visit. The blood specimen thus obtained must be submitted to an approved laboratory for a standard laboratory test for syphilis. S 144 A 490 and A 492, to amend the laws relating to vital statistics propose that a certificate of birth include in addition to the information now required by law, the following item 'Prenatal examination for syphilis, including period of gestation in months or weeks at which examination was made, and if examination was not made including reason for not making such examination' S 173 and A 106 propose as a condition precedent to the issuance of licenses to marry that each party to a prospective marriage present a physician's certificate that he or she 'has been given such examination, including a standard serological test, as may be necessary for the discovery of syphilis, made not more than 30 days prior to the' application, 'and that in the opinion of the physician the person either is not infected with syphilis, or if so infected, is not in a stage of that disease which is or may become communicable to the marital partner' A 235 proposes to exempt from the Use Tax Act of 1935 'The storage, use or other consumption in this State of orthopedic supplies' A 236 proposes to exempt from the Retail Sales Tax Act of 1933 'the gross receipts from sales of orthopedic supplies' A 342 proposes to prohibit the issuance of a license to marry unless both parties to the prospective marriage file a certificate made by a physician within ten days of the application showing that both parties are free from any contagious, infectious or communicable disease A 437 to supplement the Business and Professions Code proposes to make it a misdemeanor for any person who does not possess a physician's and surgeon's certificate or a drugless practitioner's certificate to use in any sign or advertisement the term 'drugless physician, drugless methods naturopath, naturopathic physician, sanipractor, masseur physiotherapist physical therapist diet specialist or health adviser or who uses any degree or the abbreviation relating to or standing for all or any of the foregoing terms' A 438, to supplement provisions of the Business and Professions Code relating to the practice of medicine, proposes that 'The fraudulent representation by advertisement or otherwise that a manifestly incurable condition or sickness, disease, deformity, ailment or injury of any person can be cured

constitutes unprofessional conduct within the meaning of this chapter." A 449 proposes that on and after July 1, 1940, every applicant for a physician's and surgeons or drugless practitioners certificate, or for a certificate to practice chiropody or midwifery must be a citizen of the United States. A 450 proposes to make the sale, dispensing or prescribing of dinitrophenol for therapeutic purposes a misdemeanor. A 477, to supplement the Business and Professions Code, proposes that unless a person holds a physician's and surgeon's certificate, or is licensed or authorized to use the title "doctor" or the letters or prefix "Dr.," the use of the title or letters or prefix without further indicating the type of certificate held, constitutes unprofessional conduct. A 469, to supplement the Business and Professions Code, proposes to make it unprofessional conduct within the meaning of the chapter relating to medicine, for a licensee knowingly to make or sign any certificate or other document required by law which falsely represents the existence or non-existence of a state of facts. A 478, to amend the Business and Professions Code proposes that the drugless practitioners certificate provided for by the code, in addition to the authority it now confers, shall also authorize "the general and local application or use of any and all mechanical manipulative electro-therapeutical hydro-therapeutical dietary and psychological methods of treating the sick or afflicted for any purpose including physiotherapy physical therapy, colonic therapy all methods of massage, baths and any and all other types of drugless methods of treatment for the sick and afflicted." A 484 proposes to authorize courts on the application of the people the Board of Medical Examiners or the Board of Osteopathic Examiners to restrain the unlicensed practice of medicine or osteopathy.

#### Connecticut

*Bills Introduced*—S 20 to amend the dental practice act, proposes to make it a cause for the revocation of a license to practice dentistry for the holder to advertise for patronage by means of hand bills, posters circulars stereopticon slides or motion pictures. S 57 proposes to authorize the formation of nonprofit hospital service corporations to establish, maintain and operate plans whereby hospital care may be provided at the expense of such corporations by approved hospitals to subscribers to plans formulated by the corporations.

#### Georgia

*Bills Introduced*—H 47 proposes to enact a separate naturopathic practice act and to create an independent board of naturopathic examiners. The bill proposes to define naturopathy as "a system of diagnosing and treating the human body by use of natural methods and shall include the following therapeutic measures: Mechanotherapy, hydrotherapy, psychotherapy, phytotherapy, phototherapy, thermotherapy, electrotherapy, biochemistry, and embracing such practices as massage, mineral, thermal, electrical and vapor baths, external applications and dietetics." S 4 proposes to prohibit the retail sale or distribution of amylal, veronal, luminal or any similar drugs which may have a base or be a derivative from barbital, barbiturates and barbituric acid, except on the written prescription of a licensed physician or dentist.

#### Idaho

*Bill Introduced*—S 12 proposes to authorize the Department of Health to survey and study the various industrial health hazards of the state, to devise methods for their control and to provide services to various state agencies, industry, labor, the medical profession and other organizations interested in industrial hygiene.

#### Kansas

*Bill Passed*—S 13 has passed the senate proposing to prohibit the retail sale or distribution of barbital sulphonethylmethane (trional), sulfonmethane (sulfonal), diethylsulfon diethylmethane (tetronal), carbromal, paraldehyde and chloral or chloral hydrate or chlorbutanol except on the written prescription of a duly licensed physician, dentist or veterinarian.

#### Massachusetts

*Bills Introduced*—H 320 proposes to require for all public school pupils to be examined annually to ascertain defects in sight or hearing and other physical defects tending to prevent

a pupil from receiving full benefit of school work. The eye and ear examinations are to be made respectively by ophthalmologists and otologists. H 551 proposes that applicants for licenses to marry file with the clerk authorized to issue such licenses a physician's certificate with respect to each party to a proposed marriage that each applicant has been given such examination, including a standard serologic test as may be necessary for the discovery of syphilis, made on a day not more than twenty days prior to the application, and that in the opinion of the physician the person is not infected with syphilis or, if so infected, that the disease is not in a stage whereby it may become communicable. H 756 and H 757 propose that after the removal of any limb or organ the operating physician explain to the patient or his representatives the nature and necessity of the operation performed. H 670 authorizes the department of public health to issue certificates of approval to bacteriologic laboratories and to specify in such certificates what bacteriologic or serologic procedures performed in such laboratory are approved by the department. The bill proposes to define a bacteriologic laboratory as a "place or establishment which is advertised, announced or maintained in whole or in part for the purpose of accepting for and subjecting to bacteriological study or analysis specimens of blood, sputum, urine, feces or other fluids, secretions or excretions of the body of persons ill or suspected of being ill with a disease dangerous to the public health."

#### New York

*Bills Introduced*—A 130 authorizes municipal corporations to appoint physicians, at an annual compensation of not to exceed \$750, to treat indigent persons. Apparently any qualified physician may apply for such appointment and if appointed will be subject to call in the political subdivision in which he resides or maintains his office. S 130 and A 175 propose to require every local board of health and every health officer to exercise proper and vigilant inspection of all persons, 21 years of age or over, infected with poliomyelitis and to provide at the remedial stages of the disease suitable surgical, medical or therapeutic treatment or hospital care and necessary appliances and devices for such person so infected or exposed who cannot otherwise be provided for.

#### South Dakota

*Bill Introduced*—H 10 proposes to require applicants for licenses to practice any form of the healing art, as a condition precedent to examination and licensure by their respective professional boards, to pass examinations in anatomy, physiology, bacteriology, pathology and chemistry to be given by a board of basic science examiners. Members of this board must be full time professors or associate or assistant professors, teaching the subjects of the basic sciences in any university or college in the state accredited by the North Central Association of Secondary Schools and Colleges and must not be actively engaged in the practice of healing or any branch thereof. This bill went to second reading on January 13.

#### Tennessee

*Bills Introduced*—H 183 proposes to repeal the Chiropractic Practice Act adopted in 1931. H 202 proposes to authorize sexual sterilization of such inmates of state institutions as are insane, feeble-minded or epileptic. H 203 proposes to prohibit county clerks from issuing a license to marry unless both parties to a proposed marriage file a physician's certificate setting forth that each party is free from venereal diseases so nearly as can be determined by a thorough examination and by the application of recognized clinical and laboratory tests of scientific search [sic], when in the discretion of the examining physician such clinical and laboratory tests are necessary.

#### Texas

*Bill Introduced*—S 26 to amend the medical practice act proposes, in effect to permit persons to apply or use the principles, tenets or teaching of their church in the ministrations to the sick or suffering by prayer without the use of any drug or material remedy and to charge fees for so doing.

## Utah

**Bills Introduced**—S 34, to supplement the laws relating to the practice of naturopathy, proposes that an applicant for a license to practice naturopathy must (1) be a graduate of a legally chartered naturopathic college, requiring as a prerequisite to graduation at least a four years residence course of instruction of not less than eight and one-half months each year, (2) be a graduate from a four year high school (3) have completed one year of college work in a college of liberal arts, and (4) must have a course of training of not less than twelve months in a hospital approved by the board of naturopathic physicians or, in lieu thereof a course of training for a period of twelve months in the office of a licensed naturopathic physician in the state. S 33 to supplement the laws relating to the practice of naturopathy proposes to define naturopathy as the system of treating human ailments by natural methods as taught in naturopathic colleges and includes the following: Mechano therapy, hydro therapy, physio therapy, massage, articular manipulation, Swedish movements, phyto therapy, thermo therapy, chromo therapy, vibro therapy, gynecology [sic], mineral baths, electro therapy, and obstetrics, minor surgery, organo therapy, biochemistry, dietetics, emergency use of anodynes."

## Vermont

**Bills Introduced**—H 15 proposes as a condition precedent to the issue of licenses to marry that each party to a proposed

marriage present a physician's certificate that he or she has been given "such examination, including a standard serological test, as shall be prescribed by the State Board of Health as necessary for the discovery of syphilis" and that in the opinion of the physician each party is not infected with syphilis or, if so infected, is not in a stage of that disease whereby it may become communicable. H 34 proposes to enact what appears substantially to be the uniform narcotic drug act. The bill proposes to designate as "narcotic drugs" coca leaves, opium, cannabis and every substance neither chemically nor physically distinguishable from them.

## Washington

**Bills Introduced**—S 15 proposes to enact a food, drug and cosmetic act to prevent the manufacture, shipment and sale of adulterated or misbranded food, drugs, devices and cosmetics. S 24 and H 11 propose to prohibit the retail sale and distribution of amylal, luminal, veronal, barbital, acid diethylbarbituric, para amino benzoic, sulfonamide, sulfanilamide, sulfanilic acid, prontosil, prontosil, neo prontosil, neo pronylin, or edmanlin except on the written prescription of a licensed physician, dentist or veterinarian surgeon. S 39, to amend the narcotic drug act, proposes (1) to define narcotic drugs so as to include dihydromorphone sulfate and barbital and (2) to authorize the establishment of state clinics for the treatment and rehabilitation of narcotic addicts.

## WOMAN'S AUXILIARY

## California

The auxiliary to the San Diego County Medical Society sponsored its fourth public health institute recently. The speakers included Dr Samuel J. McClendon, on contagious diseases of the school child, Harvey Stallard, DDS "Care of the School Child's Teeth," and Drs Bryant R. Simpson, Stephen A. Parowski and Rufus A. Schneiders, tuberculosis.

## District of Columbia

The educational committee appointed by the auxiliary to place a young woman in a nurses' training school in Washington has selected the Sibley Hospital Training School. Her expenses, including uniforms and equipment, are defrayed by the auxiliary. Mr Theodore Wiprud, executive secretary of the Medical Society of the District of Columbia addressed the auxiliary October 5.

## New York

The auxiliary to the Rockland County Medical Society and the society arranged a program of movies and lectures on cancer control recently. Three lectures were given by Dr John M. Swan, executive secretary of the New York State Committee of the American Society for the Control of Cancer, in the high schools of Suffern, Nyack and Haverstraw.

The auxiliary to the Albany County Medical Society met recently at St Peter's Hospital, Albany. Miss Marguerite Jacobsen, R.N., associate executive secretary of the New York State Nurses Association, spoke on the "New Nurse Practice Act." Plans were made for supplying lavettes to the Visiting Nurse Association of Albany.

## Pennsylvania

The auxiliary to the Allegheny County Medical Society held a membership rally in Renziehausen Park, McKeesport, September 14. Mrs David B. Ludwig, president, addressed the group on the aims and accomplishments of the auxiliary, and a talk on socialized medicine was given by Mrs Joseph P. Dobo.

The auxiliary to the Chester County Medical Society visited Pennhurst State School September 20. Dr George B. McC Wilson showed colored motion pictures of the school's activities.

At the tenth annual meeting of the auxiliaries of the Second Council District at Norristown Dr Frederick J. Bishop,

president of the Medical Society of the State of Pennsylvania suggested that a clipping bureau be established to collect all newspaper articles pertaining to the medical profession and that a speakers' bureau be organized.

## South Dakota

At a recent meeting of the Seventh District Auxiliary in Sioux Falls, Dr L. J. Pankow explained the new basic science law which will be voted on at the coming session of the state legislature.

## Tennessee

Through the efforts of Mrs Rogers N. Herbert, Nashville past *Hygeia* chairman of the Woman's Auxiliary to the American Medical Association, *Hygeia* is being sent to every public elementary and high school in the state of Tennessee, a total of 6,182 schools. The state legislature having appropriated funds for distributing public health literature among the schools, the Woman's Auxiliary in cooperation with the state board of education selected *Hygeia* as the magazine best fitted to be distributed under this appropriation. If any *Hygeia* chairman cares to work along similar lines, she may write to Mrs Herbert at Franklin Road, Nashville or to Mrs James D. Lester, present National *Hygeia* Chairman, Granny White Pike, Nashville, Tenn.

## Texas

At a meeting of the auxiliary to the Henderson County Medical Society at Athens, September 13, Mrs W. R. Love reviewed "The Citadel."

Socialized medicine was discussed at a meeting of the Jasper Newton Counties Auxiliary in Kirbyville, September 14.

The auxiliary to the Tarrant County Medical Society entertained the wives of physicians attending the Fort Worth Medical and Surgical Clinics September 7. Seventy-five women were in attendance. The auxiliary held a public relations tea at Fort Worth October 14. Three hundred and fifty women were present. Dr S. E. Thompson, Kerrville, spoke on socialized medicine. Presidents of women's clubs, parent teacher organizations and members of the Tarrant County Medical Society were guests at the tea.

The auxiliary to the Taylor-Jones Counties Medical Society at Abilene cooperated with the City Federation of Women's Clubs in preparing an exhibit at the county fair.

## MEDICAL ECONOMIC ABSTRACTS

## PAID NEWSPAPER ADVERTISING PROPOSED IN NEW JERSEY

At a meeting of the Committee on Public Relations of the Medical Society of New Jersey at Trenton, December 4, the advisability of a paid advertising program for the medical profession of New Jersey was considered.

The committee approved of paid institutional advertising in newspapers to acquaint the public better with the ideals, policies, program and work of the county medical societies in New Jersey. The members of the Committee on Public Relations believe that the question of paid advertising should be decided by each county medical society.

The committee recommends the inauguration of such a program by the county medical societies on a county-wide basis. The public must be told how it benefits from a system of medical practice which is free from coercion and political red tape and how politicalization of medicine will result in a poorer type of medical care for them. This proposed advertising program constitutes no departure from medical ethics. Several of the county medical societies have on occasion advertised in newspapers. What is advocated in this program is the advertising of the institution of the private practice of medicine, not the advertising of the individuals who comprise that institution. It is in keeping with medical ethics to try to preserve the best system of medical care, judged by results, which exists anywhere in the world, and to keep it free from unnecessary political restraints.

Each county can be adequately covered through a selective list of newspapers of large circulation. It is for the body of physicians of New Jersey to decide whether improved public relations, and possibly the future status of medicine itself, is worth to them an annual investment approximating the amount received from one office call.

If the county medical societies approve this suggested advertising program, the committee is prepared to undertake the preparation of advertising copy which will be a credit to the institution sponsoring it from the standpoint of both content and typography.

The Committee on Public Relations of the Medical Society of New Jersey urges that this question be placed on the agenda of county medical societies for its earliest possible consideration. The members of the committee are Drs. Joseph H. Kler, chairman, J. Berkeley Gordon, G. Barton Barlow, Edgar P. Cardwell, Homer I. Silvers and J. Allen Yager.

## THE IOWA COOPERATIVE CASE FINDING PROGRAM

The Iowa Tuberculosis Control Service, says Dr. C. K. McCarthy in the *Journal of the Iowa State Medical Society* (28:632 [Dec.] 1938), is so planned and so functions that it does not miss the infant, the child of preschool age or the child of school age. It does not miss the teachers or any persons who have had contact with a case of tuberculosis. Most important of all, it places the responsibility for the education of the public not in the public press, not in the hands of enthusiastic but often misinformed laymen but right in the hands of the family physicians who, working in conjunction with especially trained public health nurses, tell the people in the privacy of home or office the things they should know about tuberculosis. Of course the purpose of the program is to find at the earliest stage possible, those persons who have been infected by tubercle bacilli as a result of close association with an open case of tuberculosis. There are three ways of locating such individuals: through reported morbidity, through reported mortality and through personal contact with the private practitioners. In the final analysis this means that there is only one way—through the doctors. It is they who make the morbidity and mortality reports which constitute the starting point. If physicians failed to do this there would be no starting place. However, Iowa physicians do not fail.

The personnel consists of a clinic director, a supervising nurse, tuberculosis field nurses, an x-ray technician and a clerk. The

equipment consists of a portable x-ray machine and an x-ray laboratory. Never under any circumstances does the service attempt to put case finding into execution in a county until the county medical society has invited it to do so. Such an invitation must be made in writing. Furthermore, it cannot be made until after the director or some other staff member has explained the program in detail to the county medical society. It is extremely important that there shall be no misunderstanding on the part of the private practitioners as to just what the state department of health is trying to do. It was made clear that no encroachment was being made on their private practice and no attempt to force on them that specter which at times haunts all good doctors, the specter of state medicine.

The physician receives the sum of one dollar for doing the tuberculin test. This is paid by the department of health and is additional to the regular fee which the patient pays the doctor for examination.

The program has been in operation actually only since December 1937. At the present time the service is averaging a clinic a week. There are four field nurses. County nurses also are available in counties where a full time public health service is in operation, thus making it possible to double the number of surveys being conducted in a given period. Thirty-four clinics have been held since December 1937, at which 2,205 patients have been roentgenographed, all of whom had positive Mantoux tests. It is too early for statistical studies of value. Fifty-seven counties have accepted the service to date. Not a single county that has asked for an explanation of the program has failed to approve it afterward. Primarily the program was intended to serve only those counties of the state having a population of 30,000 or less. There are eighty such counties in the state.

## CAUSES OF MATERNAL MORTALITY

The minister of health was asked in the House of Commons recently whether he could make any further report on the effect on maternal mortality of the special foodstuffs granted by the special commissioners through the National Birthday Trust Fund for expectant mothers. He replied that particulars of the results of this nutrition scheme, which was now being carried on by the joint Council of Midwifery, covering the period from July 1 to Dec. 31, 1937, were now available.

They showed that among 4,446 mothers receiving special food the puerperal death rate was 0.45, the maternal death rate from associated causes 0.67, and the infant death rate (stillbirth and neonatal) 54. Among 9,040 mothers not receiving special foods the corresponding rates were 3.54, 1.33 and 83 respectively. When asked what would be the next steps in the experiment, in view of the satisfactory results already achieved, Mr. Walter Elliott said that they had to complete the experiment for which the special commissioner had given another £3,000 (*Journal of the Royal Institute of Public Health and Hygiene* 1:572 [July] 1938).

## APPARENTLY THEY DON'T WANT IT

At the meeting of the house of delegates of the Medical Society of the State of Pennsylvania, October 3-6, it was reported that Dauphin County organized a County Medical and County Dental Society Bureau directed by an experienced welfare worker and including on its staff a medical social worker and offered the people of the county a free choice medical or dental service care on a budgeted or partial fee basis, or without any charge if properly certified. Disappointed with the very slight response the bureau, at its own expense, carried advertisements in three daily newspapers and later for ten consecutive weeks a series of advertisements with accompanying explanatory articles in a labor journal of the county reaching 20,000 employed persons. Again the results were negligible.

It is quite apparent that between existing hospitals, dispensaries, clinics, physicians and dentists in private practice, without mentioning other well organized institutions and agencies the present day sickness needs, both preventive and corrective, of the people of this populous county are being met as those in need of such services will seek and accept them.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATIVE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ADDITIONAL MEDICAL COLLEGE NEWS AND ARTICLES APPEAR IN THE STUDENT SECTION, PAGE 373

### ALABAMA

**Personal**—Dr. William L. Bonks, formerly of Monticello, Tenn., has been appointed associate in charge of the division of child hygiene of the state department of health.

**Foreign Graduates Must Become Citizens**—At a recent meeting of the state board of censors of the Medical Association of the State of Alabama, sitting as a board of medical examiners, it was voted that after January 1 full citizenship papers in the United States will be required of any applicant who is a graduate of a European medical school seeking a certificate of qualification to practice medicine in Alabama.

### ARKANSAS

**Dental Health Program**—The Arkansas State Board of Health has employed fifteen dentists on part time who will conduct dental health programs in fifteen counties having full time health units, according to the *Health Officer*. These dentists will be part of the health department staff working under the supervision of the county health officer.

**District Meetings**—At the semiannual meeting of the Third District Medical Society in Marion recently, "Differential Points in the Diagnosis of Angina Pectoris and Coronary Occlusion with Therapeutic Indications of Each" were reviewed by Dr. William C. Colbert, Memphis. "Pollens Therapy in Allergic Diseases" was described by Dr. Irwin W. Barrett, Clarksdale, Miss., and "Chest Conditions in Children" were considered from the medical point of view by Dr. Walker L. Rucks, Memphis, and from the x-ray aspect by Dr. Horace D. Gray, Memphis.—The First Councilor District Medical Society recently held its seventy-second semiannual meeting in Jonesboro. Dr. Martin E. Branton, Jonesboro, showed motion pictures of the eyes, Dr. Charles D. Tibbels, Black Rock, spoke on puerperal eclampsia, and Dr. Edward R. Barrett, Jonesboro, "Amebiasis in Our District."

### CALIFORNIA

**Rabies Quarantine**—The state department of health placed a rabies quarantine on Santa Clara County December 16 with the exception of Palo Alto and San Jose. An order issued Nov. 19, 1937, had covered a portion of the county, but because of the spread of the disease it became necessary for a later order to quarantine the entire area.

**Gift for Metabolic Research**—A gift of \$50,000 has been received by the Scripps Metabolic Clinic, La Jolla, from Mrs. Harry W. Child, Helena, Mont., to be known as the Harry W. Child Memorial Fund. The income from this fund is to be devoted to metabolic research. Mr. Child, formerly president of the Yellowstone Park Transportation Company, died of diabetes in 1932.

**Society News**—The Alameda County Medical Association devoted its meeting January 16 to a round table discussion on newer concepts and procedures in tuberculosis. The speakers were Drs. Henry Chesley Bush, Livermore, chairman, Charles A. Dukes, Joseph Lloyd Eaton, Sumner Everingham, Paul C. Samson, Harold G. Trimble and Marshall B. Tucker, Oakland, and Clifford V. Mason, Livermore.

### CONNECTICUT

**Dr. Abell Addresses State Society**—Dr. Irwin Abell, Louisville, Ky., President of the American Medical Association, was the guest of the Connecticut State Medical Society at a dinner January 21 in New Haven, he discussed socialized medical developments.

**Changes in Health Officers**—Dr. Walter S. Lay has been appointed health officer of Hamden. Dr. Josephine Evarts, Cornwall Bridge, has been appointed health officer of Kent, and Dr. Reuben Rothblatt, acting health officer of Willimantic, filling the vacancy caused by the resignation of Dr. Nathan M. Spector. Dr. Howard G. Stevens, New Milford, has been appointed health officer of Sherman.

### DISTRICT OF COLUMBIA

**Society News**—A symposium on disorders of the kidneys in childhood was presented by the section on pediatrics before the Medical Society of the District of Columbia January 18, the speakers included Drs. Edgar P. Copeland, John H. McLeod, L. Clarence Rice, Jr., Hugh J. Davis and Charles P. Howze. Drs. Lawrence Kolb, Washington, and Dexter M. Bullard, Rockville, Md., participated in a symposium on narcotic addiction before the society January 11.—Ellsworth Huntington research associate in geography, Yale University, New Haven, discussed 'Effect of Climate and Weather on Human Health and Efficiency' before a meeting of medical and dental officers of the navy on duty in the District and vicinity December 5.

**Annual Graduate Clinic at George Washington University**—The seventh annual graduate clinic of the George Washington University School of Medicine will be held February 18. On the same date the annual banquet and alumni reunion of the medical school will be held at the Mayflower Hotel with Dr. Roy R. Kricke, professor of bacteriology and pathology, Emory University (Ga.) School of Medicine as the principal speaker. Those who will present papers on the clinic program include:

Dr. Charles S. White, The Establishment of a Blood Bank.  
Dr. Francis R. Hagner, Torsion of the Spermatic Cord.  
Dr. Cushtee Hall, The Smith-Petersen Nail in Intracapsular Fractures of the Hip.  
Dr. George B. Roth, An Analysis of the Proprietary Tragedy—Elmer of Sulfanilamide.  
Dr. Albert J. Sullivan, Medical Management of Peptic Ulcer.  
Drs. Theodore J. Abernethy and Harry F. Dowling, Use of Sex Chemotherapeutic Agents in the Treatment of Lobular Pneumonia.  
Dr. Walter A. Bloedorn, Popular Misconceptions in the Management of Patients with High Blood Pressure.  
Dr. Paul Padgett, Baltimore, Treatment of Tuberculous Dorsalis. Review of 900 Cases.  
Dr. Joseph I. Howard, Roentgen Therapy in Puerperal Mastitis.

Members of the District of Columbia Medical Society, members of medical societies of neighboring states and officers of the army, navy, veterans' administration and the U. S. Public Health Service are invited.

### GEORGIA

**Changes in Health Officers**—Dr. Thomas H. D. Griffith, director of the Henry R. Carter Memorial Laboratory of the U. S. Public Health Service, Savannah, has been appointed acting city health officer, filling the vacancy created November 3 by the deaths of both Dr. Victor H. Bassett, health officer, and his assistant, Dr. Alfred Larson.—Dr. Dudley A. Reekie, Louisville, Ky., field director of county health work in Kentucky, has been appointed assistant city health officer of Atlanta, it is reported.—Dr. Thomas W. Collier, Lyons, has resigned as health commissioner of Toombs County to engage in the private practice of medicine in Port Arthur, Texas.

**Special Society Meetings**—At the first annual meeting on Sea Island Beach recently the Georgia Industrial Surgeons Association was addressed by Dr. Robert Drane, Savannah, on 'Importance of the X-ray in Industrial Work', Dr. Lonnie W. Grove, Atlanta, "Organization of a Medical Service in Industry", Mr. A. B. Robertson, Atlanta, "The Problem of the Claim Men," and Mr. J. H. Allen, president of the Union Bag and Paper Company, "The Employers' Interest in Industrial Practice." Officers are Drs. Cornelius F. Holton, Savannah, president, Robert L. Rhodes, Augusta, vice president, and John W. Simmons, Brunswick, secretary and treasurer.—The Georgia Pediatric Society held its annual meeting in Augusta January 12. The guest speakers included Drs. Charles Hendee Smith, New York, Alexis F. Hartmann, St. Louis, and Thomas B. Cooley, Detroit.

### ILLINOIS

**Health Week in Moline**—The week of February 6 has been designated "health week" in Moline. A public meeting will be held February 9 with Dr. August Henry Arp, mayor, presiding. Dr. Albert C. Baxter, Springfield, acting state health director, will speak on 'The Meaning of a Public Health Department to a Community.' The observance was instigated by the Y. M. C. A. in cooperation with local medical societies, clubs and schools.

**Memorial to Physician**—A boulder and plaque were unveiled on the grounds of the Schmitt Memorial Hospital, Beardstown, recently, in honor of the late Dr. Frederick Ehrhardt. The inscription on the plaque reads: "This site was donated to Beardstown for a hospital in memory of Dr. Frederick Ehrhardt by his heirs. Dr. Ehrhardt graduated in medicine at the University of Gottingen, coming to

America in 1846. He practiced in Baltimore a year before coming to Beardstown. He died in 1881. Dr Ehrhardt was the original owner of the site given to the city for the hospital, which was dedicated in 1931.

### Chicago

**The Bacon Lectures**—Dr Walter Schiller, director of laboratories, Cook County Hospital, will deliver the Charles Sumner Bacon Lectures for 1938-1939 in the Medical and Dental College Laboratories Building, University of Illinois College of Medicine, February 15-16. His subjects will be 'Endometrioma and Endometriosis and Congenital and Acquired Sex Changes'.

**Private Physicians Carry on Syphilis Testing Program**—Under a plan adopted January 10 by the council of the Chicago Medical Society with the approval of Dr Robert A. Black acting president of the board of health, private physicians will replace physicians of the board of health in the city's syphilis testing program, it is reported. In the future, persons will be asked through educational pamphlets and lectures to go to private physicians for physical examinations, including a syphilis test the examinations for indigents to be free. Heretofore, health department physicians went into high schools, factories and neighborhood stations to make mass tests of all volunteers. In 1938 over 140,000 tests were made.

**Society News**—A symposium on disturbances of adolescence was presented before a joint meeting of the Chicago Medical and Pediatric societies January 11, the speakers were Drs Edward D. Allen, Paul L. Schroeder, Chicago, and Elmer L. Sevringhaus, Madison, Wis. At a joint meeting of the Chicago Medical Society with the Chicago Roentgen Society January 18 Dr Byrl R. Kirklin, Rochester, Minn., spoke on 'Value of Roentgen Diagnosis as It Pertains to the Physician in General Practice,' and Bernard P. Widmann, Philadelphia, 'X-Ray, Radium and Cancer'—O. C. Durham discussed 'Inhalant Allergens in the Upper Air' before the Chicago Society of Allergy January 16 and Dr Franz Alexander, 'Psychogenic Factors in Clinical Allergy'—Dr Daniel B. Kirby, New York, addressed the annual meeting of the Chicago Ophthalmological Society January 16 on 'The Surgery of the Exophthalmos'—At a meeting of the Chicago Neurological Society January 19 Drs Theodore T. Stone and Alex J. Arieff spoke on 'Temporal and Maxillary Osteomyelitis with a Report of Two Cases of Multiple Cranial Nerve Paralysis and Diabetes', John Martin, 'Studies of Ventricular Casts Made in Cases of Intracranial Tumor', and Leo M. Davidoff, Brooklyn, 'Newer Aspects in Diagnosis by the Aid of Pneumoencephalography'.

### IOWA

**Epidemic of Tularemia**—More than five times as many cases of tularemia were reported to the state department of health in November and December 1938 as in any previous year on record, according to the state medical journal for January. The distribution by counties of 100 cases of tularemia thus far reported officially is Appanoose twenty-two, Black Hawk one, Clarke one, Clinton two, Dallas one, Davis five, Decatur five, Des Moines seven, Henry two, Iowa one, Jefferson one, Johnson one, Keokuk one, Lee nine, Louisa four, Lucas four, Mahaska one, Marion three, Marshall two, Monroe two, Muscatine two, Polk seven, Ringgold one, Scott four, Van Buren one, Wapello four, Warren two, Washington three and Wayne one. It is noteworthy that with the exception of Black Hawk County no cases have been reported in the northern half of the state.

### KENTUCKY

**Society News**—Dr Edward J. O'Brien, Detroit addressed the Jefferson County Medical Society December 5 under the auspices of the Louisville Tuberculosis Association on 'Surgical Treatment of Pulmonary Tuberculosis'—Drs Eshe Asbury Cincinnati and William O. Johnson, Louisville addressed the Bourbon County Medical Society, Paris recently on 'Hip Fractures' and 'Endocrinology' respectively.

**Meeting of Psychiatrists**—Dr Floyd K. Foley, Lexington was chosen president elect of the Kentucky Psychiatric Association at its second annual meeting in Lexington December 9-10 and Dr S. Spafford Ackerly, Louisville was installed as president. Dr Lieuen M. Rogers, Lexington was elected vice president and Dr Robert H. Felix, Lexington secretary. Among the speakers were Drs Seymour D. Vestermark, Lexington, on 'Psychiatric Needs of General Practice and of the General Hospital', John W. Cronin, Lexington, 'Management of Head Injuries in Relation to the Prevention of Mental Disorder', and William K. Keller, Louisville, 'Occupational

Therapy in the Treatment of the Mentally Disordered'—A mental hygiene session open to the public was held Saturday afternoon with Dr William E. Gardner, Louisville, as chairman. The annual dinner was held Saturday evening with Frank L. McVey, L.H.D., president of the University of Kentucky, as the speaker on 'The Contribution of Culture to Healthful Living'.

### LOUISIANA

**In Memory of Dr Pierson**—A picture of the late Dr Clarence Pierson Pnevville, was recently placed in the room of medicine of the Cabildo, Louisiana State Museum, New Orleans. The inscription reads "Dr Clarence Pierson, Scientist, Builder Humanitarian, 1868-1934". Dr Pierson graduated from the Tulane University of Louisiana Medical Department, New Orleans, in 1894. He at one time served as medical superintendent of the Central Louisiana State Hospital, Pnevville, which he founded, and the East Louisiana State Hospital, Jackson. He also served as special consultant to the three eleemosynary institutions, the two already mentioned and the State Colony and Training School, Alexandria. He was a member of the House of Delegates of the American Medical Association, 1919-1920 and at one time president of the Sixth Council District of the Louisiana State Medical Society.

**Graduate Seminar**—The Graduate School of Medicine of Louisiana State University Medical Center, cooperating with the general extension division of the state university, conducted a seminar at the Lafayette Charity Hospital, Lafayette, December 2-3. The speakers included:

- Dr George W. McCoy, New Orleans, Preventive Medicine with Special Reference to Medical Practice
- Dr Charles J. Bloom, Foods for Infants
- Dr Isidore Cohn, Masses in the Neck
- Dr Charles A. Bahn, Recent Ophthalmic Advances for Practicing Physicians
- Dr James K. Howles, Some of the More Common Skin Conditions Encountered by the General Practitioner in This Vicinity, Their Diagnosis and Treatment
- Dr Henry W. E. Walther, Diagnosis and Treatment of Prostatic Disease
- Dr Daniel N. Silverman, Diagnosis and Treatment of Common Types of Diarrhea
- Dr Ben R. Heninger, Some Modern Concepts of Heart Disease
- Dr John F. Dicks, Treatment of Sterility
- Dr Valentine H. Fuchs, Ear, Nose and Throat Conditions Met by the General Practitioner
- Dr Thomas B. Sellers, Office Gynecology

### MASSACHUSETTS

**Personal**—Dr Paul I. Yakovlev, Waltham, has been appointed clinical director of the Walter E. Fernald State School, Waverley.—Edward M. East, Ph.D., professor of genetics, Harvard University, died November 9 in Massachusetts General Hospital, Boston. He was the author of 'Mankind at the Crossroads' and 'Heredity and Human Affairs'—Dr William E. Hmes, Hingham, has been appointed medical examiner of the fifth Plymouth district, succeeding Dr John G. Sweeney. The district includes Hingham, Nantasket and Hull.

**Public Lectures**—A series of free public lectures on medical subjects was begun January 8 by the faculty of Harvard University Medical School, Boston, to end March 19. The speakers include:

- Dr Leroy D. Fothergill, January 8, The Menace to Human Beings of Disease in Domestic Animals
- Dr Clarence Guy Lane, January 15, The Skin—What It Does and the Care It Needs
- Dr Tracy B. Mallory, January 22, Cancer
- Dr James J. Durrett, Washington, D. C., U. S. Food and Drug Administration, January 29, Food and Drugs—Safe and Unsafe
- Dr Harold M. Teel, February 5, Health and Hygiene During Pregnancy (for women only)
- Dr Henry N. Pratt, February 12, Asthma—Hay Fever
- Dr William C. Quimby, February 19, The Significance of Syphilis and Other Venereal Diseases
- Dr Vernon P. Williams, February 26, Nervous Breakdowns
- Dr S. Burt Wolbach, March 5, Vitamin Deficiencies
- Dr Timothy Leary, March 12, Hazards in the Modern Home
- Dr Robert B. Osgood, March 19, Chronic Rheumatism

### MICHIGAN

**Graduate Fellowship at Butterworth Hospital**—James Rowland Lowe, president of the board of trustees of Butterworth Hospital, has created a fellowship in memory of his parents, Edward and Susan Lowe, carrying with it a cash prize of not less than \$500 for graduate study by members of the medical staff who have shown increased proficiency in diagnosis and in medical or surgical treatment and fulfil other stipulations. Recipients of the award, to be known as the Edward and Susan Lowe Fellowship, must agree to expend it within one year in defraying expenses of graduate study out-

side Grand Rapids and must consult and abide by the recommendations of the staff executive committee of the hospital as to the best method of utilizing it. On his return to the hospital the holder of the fellowship is to share with the staff the knowledge he has gained by a review of his experience before a general staff meeting and other means. First award of the fellowship may be made this month.

**Secretaries' Conference**—The Michigan State Medical Society held its annual county secretaries conference at the Hotel Olds, Lansing, January 15. The speakers included:

Dr. Louis Fernald Foster, Bay City, secretary, state medical society, Michigan's Group Hospitalization and Medical Care Plans.  
Dr. Harold A. Miller, Lansing, chairman, legislative committee of the state society.  
Our legislative director.  
Mr. Lee White, Detroit, *News Detroit*, The Physician in the Press and on the Air.  
Mr. Joe W. Savage, Charleston, secretary, West Virginia State Medical Association, The Duties of a 100 Per Cent County Secretary.

Vernon J. Brown, Mason auditor general of Michigan, representing the governor, addressed the luncheon session on "The Affairs of State."

**Society News**—Dr. Russell L. Harden, Cleveland, discussed "Treatment of Anemias" before the Calhoun County Medical Society, Battle Creek, January 3.—Dr. Kellogg Speed, Chicago, addressed the Genesee County Medical Society in Flint, January 11 on the management of fractures.—Dr. Leides M. Laton, Rochester, Minn., discussed "Pain Characteristic of Various Neurologic Disorders" before the Kalamazoo Academy of Medicine, January 17.—Physicians in Van Buren County are organizing a county medical society.—Dr. Paul A. O'Leary, Rochester, Minn., discussed "Neurosyphilis and Its Treatment" before the Detroit Dermatological Society, January 16.—Dr. George E. Rockwell, Cincinnati, is the guest speaker, discussed "The Value of Oral Pollen Therapy" before the Michigan State Allergy Society in Bay City recently. Dr. Buenaventura Jimenez, Ann Arbor, is president of the society and Dr. George L. Waldbott, Detroit, secretary. Five meetings will be held during the coming year, three of which will be in Ann Arbor.—At a meeting of the Muskegon County Medical Society in Muskegon, January 20, Dr. Harry E. Mock, Chicago, spoke on herd injuries.

## MINNESOTA

**Forum on Government in Medicine**—The Minnesota State Medical Association sponsored a forum on government in medicine at the St. Paul Hotel, St. Paul, January 14. The speakers included Mr. J. George Crowhart, executive secretary of the State Medical Society of Wisconsin, Madison, and Drs. Gilbert G. Cottam and William A. O'Brien, Minneapolis.

**Personal**—Dr. Len L. Culp, Minneapolis, was recently voted life membership in the Fort Wayne, Ind. Medical Society.—Dr. Frederick P. Arny, Preston, has been appointed coroner of Fillmore County.—Dr. Charles F. McComb, Duluth, eight times elected coroner of St. Louis County, retired January 1. He is 81 years of age. Dr. John W. Ekblad was chosen to succeed him. Dr. McComb was president of the Minnesota State Medical Association in 1888, was the first president of the Interurban Academy of Medicine and was twice president of the St. Louis County Medical Society. He has practiced in Duluth since 1883.

**Society News**—The Minnesota Pathological Society was addressed January 17 by Drs. J. Grafton Love, Rochester, and Lawrence Berman, Minneapolis, on "Protrusion of the Intervertebral Disks" and "An Extragenital Chorionepithelioma," respectively. Elvin C. Stakman, Ph.D., professor of plant pathology, University of Minnesota Medical School, discussed "Virus Diseases of Plants" before the society November 15.—The Minnesota Academy of Medicine was addressed in St. Paul December 14 by Drs. Robert G. Green on "Filterable Viruses in Relation to Tumors and Malignant Growths" and Ernest M. Hammes, "Recent Progress in Neurology and Psychiatry."—The Minneapolis Surgical Society was addressed January 5, among others, by Drs. Donald C. MacKinnon on "Carcinoma of the Pancreas" and Robert G. Allison, "Radiation Therapy in Tumors."

## MISSISSIPPI

**Changes in Health Officers**—Dr. Benjamin F. Hand Jr., Greenville, has been appointed health officer of Washington County, it is reported. Dr. Littleton H. Eubanks, Lexington, assistant health officer in Lauderdale County, has been appointed in charge of the unit in Holmes County. Dr. John H. Hines, Atlanta, Ga., has succeeded Dr. Eubanks in Lauderdale County. Dr. Thomas Lon Owings, Poplarville, is acting health officer

in Pearl River County to relieve Dr. Ransom J. Jones, health officer, who is on leave of absence for study at Johns Hopkins University, Baltimore. Dr. Robert A. Clanton, Grenada, has been appointed health officer of Grenada County, succeeding the late Dr. Thomas J. Brown.

## NEW JERSEY

**Lectures on Dermatology**—A graduate course on dermatology for the general practitioner will be offered by the Bergen County Medical Society continuing each Thursday from January 2 to March 9 at Hackensack Hospital, Holy Name Hospital, Tenack, and Englewood Hospital. The lectures will be:

Dr. Richard J. Kelly, New York, Management of Acne and Seborea.  
Dr. Elias William Abramowitz, New York, Drug Eruptions.  
Dr. Leslie Paxton Barber, New York, Cutaneous and Mucous Membrane Manifestations of Syphilis.  
Dr. George Clinton Andrews, New York, Diagnosis and Treatment of Precancerous Eruptions.  
Dr. Howard Fox, New York, Diagnosis and Treatment of Common Diseases of the Skin in Childhood.  
Dr. George M. Lewis, New York, Diagnosis and Treatment of Common Lung and Infections.

## NEW YORK

**Society News**—Dr. Everett D. Kiefer, Boston, addressed the Dutchess County Medical Society, January 11 in Poughkeepsie on "Functional Disorders of the Gastrointestinal Tract."—Dr. Alexander D. Langmuir, assistant director of the bureau of pneumonia control in the state department of health, Albany, addressed the Broome County Medical Society, Binghamton, January 10 on "Higher Types of Pneumonia."—Drs. Lark E. J. Mack and Arthur E. Harris, Syracuse, addressed the Onondaga County Medical Society, Syracuse, January 3 on "Infectious Mononucleosis" and "Filterable Virus Diseases" respectively.—Dr. Alvin L. Barch, New York, addressed the Utica Academy of Medicine, December 13 on "Advance in the Therapeutic Use of Oxygen, Helium and Positive Pressure."

**Pneumonia Institute in Buffalo**—The Medical Society of the State of New York and the bureau of pneumonia control of the state department of health will sponsor an institute on pneumonia at the Buffalo City Hospital, February 16 under the auspices of the Medical Society of the County of Erie. In the morning the following program will be presented:

Dr. Edward C. Keifenstein, Syracuse, Early Clinical Diagnosis of Pneumonia.  
Dr. George M. Mackenzie, Cooperstown, Bacteriologic Diagnosis of Pneumonia.  
Dr. Jesse G. M. Bullowa, New York, Serum Treatment of Pneumonia.  
Dr. David D. Rubinstein, Albany, The New York State Pneumonia Control Program.

In the afternoon there will be a panel discussion by the four speakers with questions from the floor and practical demonstrations of the technique of serum administration.

**Legislative Committee Recommends Study of Health Insurance Before Action**—The New York State Temporary Commission to Formulate a Health Program, a committee of the state legislature, in a preliminary report adopted January 11 recommended that legislative action on a health insurance plan be postponed for another year while a broad and thorough study of the subject is being made. Eight recommendations on which action will be pressed during this session of the legislature were adopted for inclusion in the preliminary report of the commission. Briefly these are:

Establishment of therapeutic and diagnostic, tumor and cancer clinics and of a plan to make state owned radium available to approved institutions for treatment.

Extension of public health education on a broad base to include full information on the availability of health and medical facilities and services.

Encouragement of sound voluntary health and medical insurance schemes with ample provisions for record keeping and current analyses to provide the actuarial soundness of the different plans as a basis for future planning.

Provision for uniform record keeping and reporting of municipal expenditures for public health.

Expansion of public health and school nursing facilities.

Expansion of county laboratory systems or approval of existing laboratories to make diagnostic facilities available.

Amendment of the public welfare law and necessary additional appropriations to provide state aid for maternity cases.

Establishment of informal interdepartmental committees to coordinate health welfare and curative services conducted by various state and local divisions.

The commission recently held a public hearing in New York to obtain a cross section of opinion on the public health needs of the state. At its meeting in Albany Assemblyman Lee B. Mailler of Orange County was elected chairman, Senator Joe R. Hanley of Wyoming County vice chairman and Assemblyman Robert F. Wagner Jr. reelected secretary.

## New York City

**Scholarships Available for Graduate Study**—The New York Post-Graduate Medical School, Columbia University, announces that it has a scholarship fund available for qualified graduates in medicine who wish to take graduate courses at the school. By the terms of the endowment, applicants from Allegheny County, Pa. are given preference, other circumstances being equal. For information and application forms address the Director, New York Post-Graduate Medical School and Hospital, 303 East Twentieth Street New York.

**Illegal Practitioners Convicted**—Two men pleaded guilty in the court of special sessions recently of practicing medicine without licenses. Earl H. Weidling, Ozone Park, Queens, a second offender, was sentenced to three years in the penitentiary. Fake medical licenses, diplomas and certificates and a physician's automobile license plate were found in his home. J. Augustin Bombard, said to be a chiropractor, paid a fine of \$100 after admitting that he had written a prescription for a woman detective and charged her a large fee for diagnosing her pretended ailment as 'knotted nerve ends.'

**Official Tribute to Private Practitioners**—The Council of the City of New York at a meeting December 20 adopted a resolution of 'recognition of the part played by the seven thousand physicians of the city of New York for protection of the public health.' The resolution declared that 'emphasis is laid on the city work in reducing mortality and sickness through units sponsored by the city with a woful disregard of the part played by the general practitioner.' Finally it urged that the council 'take official cognizance of the great part played by the forgotten 7,000 private practitioners in this city in the reduction of sickness, disease and the death rate and deplore any attempts which may be made to minimize their great contributions.'

**Gifts to New York University**—Among gifts and bequests to New York University for medical purposes recently announced by Chancellor Harry Woodburn Chase were the following:

The de Long Corporation for the cardiac clinic fund under the direction of Dr. Clarence E. de la Chapelle, college of medicine \$12,000.  
The Commonwealth Fund for research in gynecology and obstetrics under Dr. William E. Studdiford, Jr., college of medicine \$8,299.87, also \$7,250 on account of grant to the department of preventive medicine.  
Rockefeller Foundation on account of grant for studies on influenza under Dr. Thomas Francis, Jr., college of medicine \$6,500.  
Merek and Company, Inc. for research on anesthesia under Dr. Emory A. Roventine \$1,500.  
Lucius N. Littauer for studies on pneumonia under Dr. Jesse G. M. Bullowa, college of medicine \$1,500.  
Phi Delta Epsilon fraternity to increase the Dean John Wyckoff lectureship endowment fund, college of medicine \$1,500.  
Friedsam Foundation Inc. for research in the department of urology under Dr. Meredith F. Campbell \$1,500.  
Lederle Laboratories for the Lederle Fund, college of medicine \$1,250 for the prophylaxis fund under Dr. Charles Hendee Smith, department of pediatrics \$1,050 and for the first quarterly payment of grant for research in pneumonia under Dr. Bullowa \$1,000.  
Carroll Dunham Smith Pharmaceutical Company for research in therapeutics under Dr. Arthur C. De Graff \$1,100.  
International Cancer Research Foundation for research in cancer under Robert Chambers, Ph.D., department of biology, Washington Square College \$1,000.

## NORTH CAROLINA

**Hospital News**—St. Joseph's Sanatorium Asheville, has been remodeled to care for general medical and surgical patients and will now be known as St. Joseph's Hospital. The building has four floors, two have been reserved for tuberculous patients. Obstetric patients will not be received at present. There will be ninety-six beds.

**CCC Pneumonia Patients Receive Serum**—The North Carolina State Board of Health reports that CCC enrollees and soldiers at Fort Bragg are hospitalized; their blood is typed and specific serum is administered when indicated. If the serum is not available at the hospital where the patient is undergoing treatment, arrangements have been made to obtain it from a distributor in Raleigh, it was said. In case of emergency, airplane transportation will be used for isolated and distant hospitals and stations.

**University Extension Course**—A six weeks graduate course in medicine opened in Durham January 11 to be given on successive Wednesdays. Dr. Alfred Stengel, Philadelphia, gave the first lecture, on 'Diagnostic Problems of the Abdomen' and the remainder of the series is as follows:

Dr. Paul D. White, Boston, Late Heart Disease.  
Dr. Maurice C. Pincoff, Baltimore, Blood Disorders.  
Drs. Baldwin H. E. W. Lucke and Francis C. Wood, Philadelphia, a clinicopathologic conference.  
Dr. Joseph Stokes, Jr., Philadelphia, Respiratory Infections.  
Dr. Loyal Davis, Chicago, Surgical Problem of the Treatment of Hypertension.

## OREGON

**Personal**—Dr. Charles L. Coyle, formerly of Marshfield, has resigned as health officer of Coos County to engage in private practice in Grants Pass.—Dr. Daniel C. McDonald, Hillsboro, has resigned as health officer of Washington County, Dr. Richard N. Sherwin, St. Helens, succeeded him.

**Society News**—Dr. Robert E. Mullarky, Seattle, addressed the Central Willamette Medical Society, Corvallis, November 3, on 'Peritoneoscopy'.—Drs. Laurence Selling and John E. Raaf, Portland, discussed 'Herniation of the Nucleus Pulposus and Hypertrophy of the Ligamentum Flavum' at a meeting of the Multnomah County Medical Society, January 18. Dr. Ralph A. Fenton, Portland, made the introductory remarks for a motion picture on 'Hygiene of Swimming'. At the January 4 meeting, Dr. Herbert Minor Nichols, Portland, presented a paper on 'Appendicitis: A Statistical Study Showing the Value of Early Operation' and Dr. John G. Cheetham, Portland, 'A Study of the Newer Agencies Used in the Treatment of Gonorrhea, with Special Reference to Sulfanilamide and to Hyperpyrexia.'

## PENNSYLVANIA

**Society News**—Dr. William A. Womer, New Castle, addressed the Lawrence County Medical Society, New Castle, January 5, on 'Ten Years of Syphilis: A Socio-Economic Study'.—Dr. Maxwell J. Lick, Erie, addressed the York County Medical Society at its annual banquet in York, January 12, on 'Medical Fads and Fancies'.—Dr. William Wayne Babcock, Philadelphia, addressed the Lycoming County Medical Society, Williamsport, January 13, on 'Recent Trends in Surgical Practice.'

## Philadelphia

**Annual Oration in Urology**—Dr. Gilbert J. Thomas, clinical associate professor of urology, University of Minnesota Medical School, Minneapolis, delivered the B. A. Thomas Annual Oration of the Philadelphia Urological Society, January 17, on 'Changing Concepts of Urogenital Tuberculosis.'

**Director of Health Appointed**—Dr. Charles F. Nassau, clinical professor of surgery, Jefferson Medical College, has been appointed director of public health of Philadelphia to succeed Dr. William C. Hunsicker, who died January 10. Dr. Nassau, 71 years old, graduated from the University of Pennsylvania School of Medicine in 1891 and Jefferson Medical College in 1906. He is chief surgeon at Frankford Hospital, surgeon to St. Joseph's Hospital and Girard College and assistant surgeon to Jefferson Hospital.

**Society News**—Dr. Herbert Fox, among others, addressed the Pathological Society of Philadelphia, January 12, on 'Primary(?) Tuberculosis of the Spleen: Inclusions in Giant Cells in Tuberculosis(?) of the Spleen'.—At the annual meeting of the Philadelphia Pediatric Society, January 10, Drs. Irving J. Wolman, Rachel Ash and Ralph S. Bromer spoke on 'Diagnosis of Congenital Cardiac Defects in Infancy' and Dr. Bernard L. Kahn, on 'Congenital Ectodermoses in Infancy and Childhood'.—Drs. John F. McCloskey and James A. Lehman addressed the Philadelphia Academy of Surgery, January 16, on 'Living Fascial Suture in the Repair of Large Inguinal Hernias'.—Drs. Burtis M. Hance, Easton, Pa., and Walter W. Baker addressed the Philadelphia Urological Society, December 19, on 'Suprapubic Prostatectomy and Its Relationship to Infection' and 'Surgical Treatment of Horseshoe Kidney' respectively.

## UTAH

**Meningitis Among Indians**—The Associated Press reported January 14 an epidemic of meningitis among Indians of the Navajo reservation which occupies parts of Utah, New Mexico, Colorado and Arizona. There have been fifteen deaths. The Utah State Board of Health warned travelers to avoid the reservation; it was said.

## WASHINGTON

**Personal**—Dr. John R. Corkery, Jr., has resigned as health officer of Spokane to engage in private practice. Dr. Fred Charles Harvey succeeded him.

**Seminar in Internal Medicine**—Dr. Dwight L. Wilbur, San Francisco, conducted a seminar in internal medicine at the Seattle General Hospital, December 28-30. Among the subjects of his lectures were recognition and treatment of vitamin deficiency states, differential diagnosis and treatment

of gastrointestinal bleeding, nervous indigestion, peptic ulcer and the Vitamin B complex in medicine with particular reference to thiamin chloride and nicotinic acid Dr Wilbur addressed a special meeting of the King County Medical Society December 28 on "Recent Advances in Nutrition"

### WISCONSIN

**Intercity Meeting**—The Interurban Academy of Medicine held its annual meeting in Superior November 16 with Dr Charles H Slocumb, Rochester, Minn., as the speaker on "Diagnosis and Treatment of Rheumatism" Dr David L Tilderquist, Duluth, was elected president and Dr Frank J Elias, Duluth secretary

**Group Hospitalization**—At the midwinter conference of the Wisconsin Hospital Association in Milwaukee January 11 a special committee was appointed to study group hospitalization plans and to promote legislation permitting it. In a resolution proposing this action the Rev Herman L Frischel, superintendent of the Milwaukee Hospital pointed out that the state medical society had recently approved the principle of the plan. Fees proposed were 75 cents per month for each member for full coverage, 50 cents per month for the first dependent and 25 cents each for additional dependents. Hospitals would provide care for twenty-one days, including board and room in a three or four bed ward general nursing and operating room services, all formulary drugs and an \$8 allowance for serums, surgical dressings, limited laboratory and x-ray services and special services such as oxygen therapy, diathermy, ultraviolet and radiant heat treatments. Not included would be chronic ailments such as mental disease and tuberculosis

### GENERAL

**Editor of Surgical Journal Appointed**—Dr LOVEL DAVIS, professor and chairman of the department of surgery, Northwestern University Medical School, Chicago has been appointed editor of *Surgery, Gynecology and Obstetrics* to fill the vacancy caused by the death of Dr Allen B Knavel. Dr Davis was made assistant editor of the journal in 1927 and associate editor in 1933. He graduated at Northwestern in 1918.

**Grants Available to Aid Research**—The Committee on Scientific Research of the American Medical Association invites applications for grants of money to aid in research on problems bearing more or less directly on clinical medicine. Preference is given to requests for moderate amounts to meet specific needs. For application forms and further information please address the committee at 535 North Dearborn Street Chicago.

**Physicians Wanted**—Physicians throughout the country are invited to compete for positions in the Michigan State Service. Positions are open as hospital physician and public health physician at salaries ranging from \$200 to \$240 per month, less maintenance. Women physicians in particular are sought. The examination will be held in the near future and those interested are urged to communicate at once with the Michigan Civil Service Department, Lansing, Mich., for application blanks and additional information.

**History of Science Meeting**—The History of Science Society in cooperation with the American Historical Association met at the Palmer House Chicago, Dec 29-30 1938. The speakers included

Dr Arno B Tuckhardt Chicago Dr William Beaumont and the recently acquired Beaumont Memorabilia of the University of Chicago  
Dr Ko K Chen Indianapolis Chair of the South American Indians  
Dana B Durand PhD Cambridge Mass Science and Philosophy in Late Scholasticism  
George de Santillana Winthrop Mass The Emergency of Scientific Concepts in History—Machivelli  
George Sarton LI D Cambridge Comenius and Bayle

**Macy Foundation Grants for Medical Research**—During 1938 the Josiah Macy Jr Foundation made grants aggregating \$175,420 for medical research to thirty institutions in Europe and the United States. At the annual meeting in December it was announced that Mrs Walter G Ladd who established the foundation in 1930 in memory of her father, had made a substantial gift in further support of the work. Drs Stanhope Bayne-Jones, New Haven, Conn., and Charles Sidney Burwell, Boston, were elected to the board of trustees.

**Prints of "Beaumont and St Martin"**—John Wyeth and Brother, Philadelphia has about 3,000 reproductions of "Beaumont and St Martin" that are available to physicians on request. The picture shows Dr William Beaumont at Fort Mackinac drawing gastric juice from the fistula in Alexis St Martin's side. The pictures contain no advertising and are

suitable for framing. The original painting, by Dean Cornwell, owned by John Wyeth and Brother, is done in oil and is the first of six large paintings commemorating "Pioneers of American Medicine," sponsored by Wyeth and Brother. Mr Cornwell will be the artist.

**Dana Medal Awarded to Dr Alger**—The Leslie Dana Gold Medal, awarded annually by the Association for Research in Ophthalmology and the St Louis Society for the Blind, was presented to Dr Ellice M Alger, New York, December 1 at the annual meeting of the National Society for the Prevention of Blindness. Dr Alger was honored for his contributions to ophthalmology during the past thirty years and his work as a teacher. A graduate of the University of Vermont School of Medicine in 1893 Dr Alger taught at his alma mater and at the New York Polytechnic Medical School. For many years he has been professor of clinical ophthalmology at New York Post-Graduate Medical School and Hospital.

**Society News**—The annual national conference of the Progressive Education Association will be held in Detroit at the Book-Cadillac Hotel February 22-25. The International Council for Exceptional Children will meet in conjunction with the association. Dr Walter B Cannon, Boston, was elected president of the American Association for the Advancement of Science at its midwinter meeting in Richmond, Va., December 27-31. Dr Carl J Wiggers, Cleveland was elected vice president and chairman for the section on medical sciences (N). Dr Edmund R Long Philadelphia, was elected a member of the executive committee to succeed the late Dr Earl B McKinley. Dr John F Fulton, New Haven, Conn., was elected president of the Association for Research in Nervous and Mental Diseases at the annual meeting in New York December 27.

**Examinations by Obstetric Board**—The general oral clinical and pathologic examinations for all candidates, part II examinations (groups A and B) will be conducted by the American Board of Obstetrics and Gynecology meeting in St. Louis, May 15-16 immediately prior to the annual meeting of the American Medical Association. Notice of time and place of these examinations will be forwarded to all candidates well in advance of the examination dates. Candidates for reexamination in part II must request such reexamination by writing the secretary before April 1. Candidates who are required to take reexaminations must do so before the expiration of three years from the date of their first examinations. Applications for admission to group A in the May examinations must be on file in the secretary's office by March 15. Application blanks and booklets of information may be obtained from Dr Paul Titus secretary, 1015 Highland Building Pittsburgh.

## Government Services

### Snow Medal Awarded to Dr Parran

The American Social Hygiene Association has awarded the 1939 William Freeman Snow Medal to Dr Thomas Parran, surgeon general, U S Public Health Service "for his great contribution to the health and happiness of the American people through his persistent efforts against syphilis and the conditions which favor its spread." Presentation of the medal will be made by Dr Livingston Farrand, Brewster, N Y, as part of the National Social Hygiene Day program at the Hotel Mayflower, Washington, February 1. The social hygiene society of the District of Columbia will be host to the national organization. Mrs Franklin D Roosevelt and Dr Parran will be the principal speakers.

### Changes in U S Public Health Service

Dr Frederick J Krueger has been promoted and commissioned as passed assistant surgeon in the regular corps of the U S Public Health Service. The following have been appointed and commissioned as assistant surgeons in the regular corps: Drs Albert Gallatin Love Jr, Waldron M Senott, Kenneth M Joyce, John P Turner and Walter E Sharpe Jr. Included among those appointed and commissioned as assistant surgeons in the reserve corps are Drs Harms W Bloemers at U S Marine Hospital, Detroit, Edwin E Corcoran at U S Public Health Service Dispensary, Washington, and Bothwell Graham III at U S Marine Hospital Staten Island, N Y.

### LONDON

(From Our Regular Correspondent)

Dec 31, 1938

#### Physicians' Practices in Case of a National Emergency

Physicians are becoming increasingly concerned as to their practices in the event of a national emergency. Some of the problems to be solved are (1) arrangements at first aid posts for surgical assistance (at the time of the crisis experienced surgeons were to be allotted to hospitals only, but it has been suggested that senior medical students might man the first aid posts), (2) whether physicians will be asked to report at once to a local station and whether they will be organized by the civil defense department or carry out their own organization and (3) remuneration for services (if physicians are needed for public work they will be unable to carry on private work and must look to the authorities for maintenance).

The British Medical Association has prepared a model scheme for the protection of the practices of physicians who in time of national emergency are engaged in whole time war service. The intention is to protect the capital value of the practice of an absentee physician and to insure that 50 per cent of the money received for the treatment of his patients while he is on service and for an agreed period thereafter shall be paid to his legal personal representative, less an approved deduction for administrative expenses. The scheme will be effective only if the majority of the physicians in the area agree to join in the communal arrangement. It is strongly desired that all in the area shall agree to join, as any other method will almost certainly lead to confusion and loss. Thus the nomination of one physician to conduct the practice of an absentee would not completely protect his interests. Some of his patients might decline to be treated by the nominee, or his illness or death might bring the arrangement to an abrupt end with serious depreciation of the capital value of both practices. The evacuation on a large scale of places such as cities specially liable to air raids will require a considerable amount of accountability in the allotting of capitation payments for insured persons under the panel system, for which it is proposed to establish a bureau. In London the British Medical Association has formed a local emergency committee to deal with all these matters. In case of war this body will become the local medical war committee and will deal with the recruitment of physicians.

#### Roentgenographic Appearances of the Lungs in Measles

The roentgenographic appearances of the lungs in measles were first described by Kohn and Koriansky in 1929 who observed in 55 per cent of the cases shadows suggesting infiltration, which varied in type, being disseminated mottling in various areas, large homogeneous triangles or large opacities obscuring the hilar and paravertebral regions. These changes frequently occurred in the preeruptive stage suggesting an intimate association between pulmonary infiltration and the disease rather than a secondary infection. The health officer of the London County Council, Sir Frederick Menzies, has published a series of researches on the measles epidemic of 1935-1936 made in the council's hospitals for infectious diseases. The fifth report which has just been published, is a monograph on the roentgenographic appearances of the lungs in measles by M. F. Covey, assistant medical officer of the North-Eastern Hospital and A. C. Dixon, visiting radiologist. Routine examination of all patients was not attempted but sixty-one children showing definite clinical evidence of pulmonary involvement usually bronchopneumonia, were selected. In the majority of cases roentgenograms were taken when clinical signs were no longer present and the patient was well advanced in the convalescent stage. In some cases however they were made when the tem-

perature was raised or signs of bronchopneumonia were present. The object was to detect pulmonary changes of a temporary or permanent nature when the patient had recovered from measles.

In every case roentgenographic signs were present. In 62.3 per cent there were no physical signs in the lungs and the temperature had subsided at the time of roentgen examination, in 14.7 per cent there were still pyrexia and signs of bronchopneumonia, in 18 per cent there were a few coarse rales but no pyrexia and in 5 per cent there were no physical signs but mild pyrexia. The roentgenographic changes corresponded with those noted by Kohn and Koriansky and included (1) pulmonary infiltration (fine mottling or coarser infiltration at the bases), (2) increased hilar shadows in all cases, (3) abnormal intensity of the pulmonary markings and (4) pleuropulmonary changes. The results emphasize the importance of keeping under roentgenographic observation for a considerable time all patients who have had bronchopneumonia as a complication of measles, as the probability of permanent changes is much greater than is usually supposed. In many cases the changes were present at the time of the patient's discharge from the hospital and were suggestive of permanent damage. It is proposed to extend the roentgen examination of the chest during the next epidemic of measles.

#### Graduate Courses for Panel Physicians

More than 1,100 panel physicians attended graduate courses in 1938. Next year the number will be increased to more than 1,500. The course lasts a fortnight and is held at sixteen medical centers in all parts of the country. The year 1938 was the first complete year for the working of the scheme. So eager were the panel physicians to avail themselves of these courses that three times as many applications were received as there were vacancies. The cost is defrayed by the national health insurance funds. Grants are made to cover the fee for the course, traveling expenses, subsistence allowance and the payment of a locum tenens when one is necessary. The courses are arranged by the ministry of health after consultation with an advisory medical committee. The arrangements for the selection of individual physicians are made through the insurance committee of the British Medical Association. It is hoped to arrange courses at five year intervals for all panel physicians who wish to take advantage of them. The object is to keep the physicians down to date in the advances of medicine more efficiently than can be done merely by reading. Hence physicians are not eligible until they have been qualified more than five years. More than half the courses in England are held at the British Postgraduate Medical School, London, which will provide continuous courses from March 7 onward.

#### Research on the Atmosphere in Mines

Recent work on silicosis and dust in coal mines, methods of suppressing dust in the air, underground illumination and the pressure and quantity of firedamp in coal seams are the subject of a report by the Director of the mining research laboratory. Attention is called to the close connection between the high incidence of bronchitis and silicosis in the western area of the South Wales coal fields. A probable cause is the subjection of the miners still hot and perspiring after their work to the cold blast of air in the riding spakes. Another possible cause is daily exposure to small quantities of nitrous fumes after shot firing.

Investigations have been made of the dust suspended in air and the methods for its suppression during the driving of hard headings or when there is ripping in rock. A great reduction in concentration was found to be produced when dust traps were in use or when wet drillings were employed. Ventilation in which the vitiated air is withdrawn through tubes by means of a suction fan or by the ventilation pressure of the pit has the great advantage that the workmen are not exposed to harmful dust or fumes. In many cases the dust used for stone dusting was unnecessarily fine and in view of its harmful effect such

a large proportion of particles of a size less than 5 microns is deprecated. In the removal of coal dust and water mist was found much more efficient than a spray, it gave an efficiency of the order of 90 per cent. Where the dust is highly siliceous and a respirator capable of filtering out the finest particles is necessary. A high air velocity for increasing the cooling power at the working face was found to have the drawback that with velocities greater than 600 feet a minute the amount of dust carried became a nuisance.

#### Terminal Disinfection

At the Society of Medical Officers of Health an important discussion on terminal disinfection and the exclusion of contacts from school was opened by Dr. Duncan Forbes, health officer for Brighton. He pointed out that the persistence of anthrax bacilli in hides for years and of tubercle bacilli in dried sputum and dust for months gave rise to the mistake that infection lived on in bedding, clothes and the like. But the discovery of diphtheria carriers and of mild overlooked cases of scarlet fever and of carriage of infection by spray showed that apparently healthy carriers were the chief cause of the spread of scarlet fever and diphtheria and that the part played by fomites was negligible. On these grounds orthodox disinfection of mattresses and bedding was abandoned in Brighton in 1910 and spraying in 1921. The boiling of sheets, washing of blankets, dusting of bedrooms and scrubbing of floors was substituted. Home contacts after measles have not been excluded from school at Brighton since 1922, as this did not prevent general infection of the school, and the excluded children played with and infected neighbors' children.

Dr. Andrew Topping said that terminal disinfection was a survival from times of complete ignorance of how infection was spread. We now knew that organisms responsible for infections were extremely short lived outside the human body and that infection did not normally lurk behind picture rails or in the depths of a mattress but is almost invariably due to carriers. But under certain circumstances microbes—for example hemolytic streptococci—could survive outside the body for considerable periods. Recent experiments at Queen Charlotte's Hospital showed that they could be recovered from dust. The moral was: Remove the dust. There was no better way than a liberal use of soap and water.

#### PARIS

(From Our Regular Correspondent)

Dec 24, 1938

#### Lectures on the Ultraviruses

Professor Levaditi, director of the Gournier Institute of the Pasteur Institute of Paris, has organized a course on the status of our knowledge of the ultraviruses. The lectures will be given by Professor Levaditi aided by Drs. Lepine, Mollaret, Magroux and Paie and the subjects will be the virus of variola, herpes, rabies, encephalitis, yellow fever, poliomyelitis, Nicolas-Favre disease and choriomeningitis, the ultravirus of certain diseases in animals, the ultravirus of vegetal cirruses, chemico-physical methods applied to the study of the ultravirus and general considerations on the action and composition of ultraviruses. The first lecture will be given January 6 at the Pasteur Institute of Paris.

#### Promotion in Legion of Honor for Bacteriologist

During the dedication ceremony incident to the opening of the new buildings of the Pasteur Institute at Garches, a suburb of Paris, the minister of public health conferred the rank of commander of the Legion of Honor on Prof. Gaston Ramon, director of the branch. This honor is a well merited recognition of his work during the past fifteen years in immunology, especially the more recent contributions, such as vaccination against diphtheria and tetanus by the respective toxoids.

#### Dedication of Branch of Pasteur Institute

The older quarters of the branch of the Pasteur Institute at Garches having been found inadequate to house its rapidly increasing activities, a large new addition was built. The opening of the new laboratories was marked by an elaborate ceremony presided over by M. Rucart, minister of public health. After Dr. Louis Martin, director of the Pasteur Institute of Paris, had recalled the fact that diphtheria antitoxin was first prepared at Garches, Professor Ramon stated that the rapid development of serotherapy and of the use of toxoid vaccination methods had necessitated the construction of more adequate quarters.

Attention was called to the fact that the use of the toxoid to vaccinate children against diphtheria had resulted in a drop in the mortality rate of 75 per cent in ten years in Paris where only one half of the children had been vaccinated, and of more than 90 per cent in New York, where 80 per cent of the children had been vaccinated. The mortality in Canada has been practically eliminated, nearly every child is now being given three doses of the toxoid as a prophylactic measure against diphtheria. Vaccination of French army horses against tetanus with the specific toxoid has been followed by absolute suppression of the disease during the past ten years. Since August 1936 antitetanus vaccination with the specific toxoid has been made obligatory in the French army. Every soldier is given an 'associated' vaccination against typhoid, diphtheria and tetanus. A visit to the laboratories at Garches, where all the serums and toxoids now distributed by the Pasteur Institute of Paris are elaborated, will be of interest to every one interested in immunology. Garches can be reached by automobile in about twenty minutes from the center of Paris.

#### Effects of Lowering of Atmospheric Pressure

Experiments on human and animal subjects have been made here during the past few years to note the influence of a lowering of the atmospheric pressure as encountered by aviators at very high altitudes. At the Oct. 25, 1938, meeting of the Academie de medecine of Paris, a report of experimental observations was submitted by Dr. Cluzet and his co-workers. Special attention was devoted to the analytic and graphic study of electrocardiographic disturbances as well as to alterations of blood pressure. Experiments were carried out in a caisson to create an atmospheric depression corresponding with rabbits and dogs to that at altitudes of between 10,000 and 11,000 meters (30,000 to 35,000 feet) and with human subjects to that at altitudes not exceeding 6,500 meters (20,000 feet).

In the first series, the influence of such artificially produced lowering of the atmospheric pressure revealed itself in marked changes in the electrocardiogram, which indicated failure of the right ventricle followed by total myocardial impairment. These electrocardiographic changes disappeared after inhalation of oxygen or of the mixture of oxygen and carbon dioxide proposed by Yandell Henderson. An adjuvant therapeutic action of less importance was noted after intravenous or subcutaneous injection of either strychnine or acetylcholine or both of these drugs.

In a second series of experiments, observations were made on the influence on arterial tension of gradual increases in the artificial lowering of atmospheric pressure. Until the pressure corresponded to that at an elevation of 8,000 meters (about 25,000 feet) a progressive rise of the blood pressure was noted. Above this altitude there is a more or less sudden drop in the blood pressure, which is indicative of a severe cardiac failure. Both in man and in animals the inhalation of oxygen as well as that of the carbon dioxide oxygen mixture suppresses almost completely the rise in blood pressure.

up to an altitude of 8,000 meters as well as the tendency to a drop in blood pressure above this altitude. Intravenous injections of strychnine sulfate and acetylcholine apparently do not modify the hypertensive effect of diminished atmospheric pressure in animals up to an altitude of 8,000 meters. On the contrary, at altitudes above 8,000 meters a noteworthy increase in the blood pressure is noted in animals instead of the customary drop above this altitude.

The practical conclusions of these experiments are that they confirm the favorable influence of inhalations of oxygen and of the carbon dioxide-oxygen mixture on cardiovascular disturbances at high altitudes. The differences in the action of oxygen and the carbon dioxide-oxygen mixture are too slight to indicate that the reaction of the carbon dioxide-oxygen mixture is better. Inhalations of either oxygen or the carbon dioxide-oxygen mixture will suffice to prevent cardiovascular disturbances in aviators if they are employed above an altitude of 6,000 meters. From this altitude upward, inhalations of oxygen or of the carbon dioxide-oxygen mixture are difficult to carry out, but this is not true of injections of strychnine and acetylcholine, which should be used as substitutes above this altitude.

#### News of the Universities

Since the last report on the universities (THE JOURNAL July 9, 1938, page 184) interesting developments have taken place. National Minister of Education Rust, in opening the university congress at Leipzig spoke of the early antagonism of the universities to the Nazi revolution, which, he said, was based on misunderstanding. The goal is not a material domination of the universities, the schools themselves must spontaneously espouse the doctrine of German racial superiority. Institutions of higher learning are primarily concerned with training students for various professions, whereas the new German state has in hand their spiritual orientation. It is no longer a question of whether or not the universities should continue in existence, it is a question of their reorganization. Minister Rust declared that it is often better to march along the street in a column than to engage in discussions. No one wishes to deprive the scholar of his quiet workroom but there must be a natural interrelation of scientific endeavor and the nation as a whole.

At a festival at Cologne University, Rust stated that the racial theory of the new German reich is opposed to the idea extolled by a French cabinet minister at the dedication of a memorial to the Jewish war dead at Verdun. By the concepts of liberty and equality which stem from the French Revolution reason was enthroned as the most sovereign authority. However this ideology later became the source of marxism and bolshevism. Human reason could never set up for itself the law of heroism. Whoever proclaims the principle of personal liberty as the basis of a government will never be able to make supreme the power of the state. Nazism had to face the fact that the disastrous concepts of liberty and equality were prevalent in German universities. Hitler has established a new fundamental concept, namely, a nation based on race. Rust advocated continuation of the old German universities in the belief that Germany stands today on the threshold of an era of greatness. But a university based on purely scientific principles alone ought not to survive. The school must be thoroughly Nazi, for otherwise it cannot keep abreast of the times. The minister expressly wished this last remark to be understood as an appeal.

At the Congress of German Students in Heidelberg an official report was circulated which said that every student should work for a time on a farm or in a factory, an experience of paramount importance for the acquisition of self discipline and political maturity. During the summer vacation of 1937 more than 9,800

students, men and women, put in eight weeks working on farms. At the same time more than 1,100 students worked in factories and thus enabled 2,100 regular industrial workers to take 21,000 extra days off.

#### WAR AGAINST INTELLECTUAL PARTICULARISM

At the same congress Dr. Scheel, national führer of students, stated that war should be waged against intellectual particularism. Although German students recognize the function of a university, their understanding will be incomplete if the school is not thoroughly imbued with the Nazi philosophy. The university stands in constant danger of degenerating into a purely intellectual institution, whereas its true function is that of a training center. In future the sharply outlined obligatory 'pattern of manhood' will certainly rest on more than an academic basis. It must be made plain to the youth of Germany that science, far from being a useless occupation, represents an important phase in the struggle between the Nazi weltanschauung and its adversaries.

#### STUDENT AID

The national government has created a "National Student Aid" based on student benefit organizations, which will be concerned with the economic and physical welfare of the new academic generation. Its president is the national führer of students. The funds are obtained from government subsidies, from volunteer contributions and from officially regulated contributions by the student bodies. Of the total of about 60,000 university students, the number receiving aid is constantly about 6,000, and 700 of these are helped throughout their student careers. Another 1,500 students are helped by the local student aid services in collaboration with the central organizations. Another 2,000 students are admitted to free meals and other benefits. About 1,500 special scholarships are awarded annually, the largest being grants of 1,200 marks to certain students preparing for final examinations. The assets of the National Student Aid in 1938 amounted to around 4,000,000 marks exclusive of the funds of the local organizations in certain universities.

#### NAZI ALUMNI AND STUDENT ORGANIZATIONS

In the past, alumni members of student fraternities were organized into special associations of "old grads," which served to keep alive old academic contacts and to aid the undergraduate members of the respective clubs. These alumni groups were a traditional part of the German university. As previously reported, all these alumni groups had been disbanded. Recently, however, they have been revived under government auspices and united into a German students' alumni association. This step represents the fruition of special efforts made by the government to appease the university alumni. The "Nazi alumni association" now sole organization of university alumni in Germany, held its first rally in Heidelberg. It was announced that all Catholic organizations of students and alumni had been disbanded and their funds confiscated "for the benefit of organized Nazi activities among students." An enormous increase in the membership of the Nazi alumni association has lately been made known, in 1937 there were some 7,000 members and at present there are nearly 50,000.

The Heidelberg rally was also the occasion for an address by Dr. Scheel, who spoke of the social clubs which have replaced the old student fraternities as "cells of the Nazi party." He also remarked that the survival of academic life depended on the adaptability of the universities to the Nazi movement.

#### THE YOUNGER ACADEMIC GENERATION

An acute problem is that of aid for the younger academic generation. The national führer of university instructors, Dr. Schulze, some time ago submitted a report saying that the shortage of young professional men was due to the exodus of university students into business following the Nazi accession.

The universities were unable to keep pace with the speedy tempo of new developments. Then too the remuneration offered the young men by the universities could not compete with that offered in the industrial field. Five months later Dr. Schultze stated that with respect to the filling of teaching posts and the numbers of the younger academic generation the needs of the universities were not being met. Since 1935 the young graduates in engineering have not been able to meet the demand. He requested that people desist from unjustified criticism of universities.

The decreases in enrolment in the universities is shown by a report on Bavarian institutions. Students admitted to the first semester numbered 2,957 in the summer semester of 1931, but in the winter semester of 1937-1938 the number was only 940. In the winter of 1913-1914 a total of 9,340 students were matriculated, the number was 13,819 in the winter of 1932-1933 and only 6,825 in the winter of 1937-1938 and 6,092 in the summer of 1938. The enrolment in the past year was far below that of prewar times. Moreover, the number of medical students has dropped from 593 in 1928 to 240 in the summer of 1938. To counteract this dearth of younger professional men an abbreviation of the time spent in study was proposed. A decree of the national minister of the interior has already reduced the medical course by about one semester, the entire course now covers ten half year periods instead of eleven.

As to the new generation of university teachers, an endeavor is being made to remedy the depletion of their ranks. As stated in the article "Qualified for a Professorship" (in *Nat.-Soz. Parteikorrespondenz*) there is no need for a meticulous investigation of a teacher's past prior to 1933 and one must differentiate between a single misstep and an antigovernment attitude of mind.

#### DECREE AGAINST JEWISH STUDENTS

In November, after the assassination of von Rath in Paris, all Jews (an extremely small number) who had been allowed to attend the universities were summarily expelled. The few Jewish pupils remaining in the public schools were similarly dealt with. Likewise all loans to Jewish students were immediately called in.

#### AUSTRALIA

(From Our Regular Correspondent)

Dec 20, 1938

#### National Insurance Postponed

Following a parliamentary crisis in which a move was made to shelve indefinitely the scheme for national health and pensions insurance in Australia, its introduction has been postponed until September 4, nine months later than originally planned and four months later than the date fixed under the amended legislation. This step has been forced on the government by pressure from a powerful section of the Country Party, whose claim is that the record defense expenditure of £63,000,000 combined with low price levels for primary production make postponement imperative in the interests of the people. Concessions made to the Country Party during the recent crisis include the introduction of new legislation to provide benefits for small employers and self-employed persons, but there is still a powerful faction determined to fight for the definite postponement of the entire scheme. It has also been suggested that the whole scheme be redrafted and reconstituted, but it is unreasonable to suppose that a second scheme could be formulated under present conditions which would be more generally acceptable.

#### College of Physicians

The inaugural ceremony of the Royal Australasian College of Physicians took place December 13 in the great hall of the University of Sydney. Fraternal messages were received from the Royal College of Physicians of London, the Royal College of Physicians of Edinburgh, the American College of Physicians

and the Royal Australasian College of Surgeons. Great interest was attached to the occasion by the inclusion in the inaugural program of a valuable series of lectures and demonstrations.

#### Training of "Nursing Aids"

The department of health in New Zealand has been considering the question of the training of nursing aids for work among the chronic sick and, in consultation with the Nurses' and Midwives' Registration Board, has prepared a scheme with this object in view. To show the necessity for the proposal it may be stated that according to the last census about 140 women who were not registered nurses and who had either no training or very little were engaged in private nursing in the dominion. It will be the function of these "nursing aids" to care for the chronically ill. The proposed scheme will have the additional advantage of bridging the gap between leaving school and entering a hospital for general training. On completion of the course in nursing aid, a concession in time will be allowed toward general training if the student wishes to proceed further. The course covers two years and conforms to the regulations prescribed by the Nurses' and Midwives' Registration Board. The first year's practical experience will be devoted to a training in domestic arts and will include experience in domestic duties, laundry and kitchen. The second year will be spent in the wards of an approved hospital and will include experience in the personal care of the patient and general ward hygiene. Theoretical instruction will include in the first year hygiene, an elementary introduction to anatomy and physiology, and the principles of cooking and nutrition and in the second year a series of lectures on the principles of general nursing and first aid. Similar schemes for the training of "nursing aids" have been tentatively tried out in the United States of America, Great Britain and Canada, but in no country so far has any such comprehensive scheme as is now contemplated been put into force.

#### POLAND

(From Our Regular Correspondent)

Jan 3 1939

#### Spotted Fever Epidemic

Spotted fever has broken out from time to time in the eastern districts of Poland, particularly Polesie, because of the great number of lice harbored by the country folk living there. Dr. W. Skomoroch has reported on some peculiarities in the clinical picture in many cases he recently observed. The disease started, as usual, with headache, uneasiness and a rise in temperature. The temperature kept at a high level for a fortnight and then dropped abruptly. The Weil-Felix test was positive. The most striking feature was the complete absence of any rash. Another unusual feature was the absence of nervous disorder. The mortality rate was relatively low, about 5 per cent. No case of enlargement of the spleen or desquamation was observed.

#### Complications Following Spinal Punctures

Dr. I. Suss of the neurologic clinic of the University of Cracow reported statistical data concerning complications following spinal puncture. The material consisted of 2,913 punctures done in the clinic during the last eighteen years. Of these 2,817, or 96.7 per cent, were lumbar, while seventy three, or 2.5 per cent, were suboccipital and twenty three, or 0.7 per cent, were intraventricular. Complications occurred in 216 cases, or 7.4 per cent. The complications were fatal in twelve cases, ten of lumbar puncture and two of intraventricular puncture. In nine of the ten fatal cases brain tumor was found by post mortem examination. In these cases the cerebellum was squeezed into the foramen occipitale magnum and the tumor was found in the fossa cranii posterior. In all the cases the death occurred immediately or, at the latest, within four days after the puncture. The death was preceded by bradycardia, diminishing of the pulse, paleness of the skin and vomiting. In some cases the temperature rose remarkably before death, in others

the author observed spastic hemiplegia followed by a deep coma. In the two cases of intraventricular puncture death was due to faulty technic, in one it was attributed to hemorrhage caused by a lesion of a brain vessel and in the other a large amount of air was introduced into the ventricle, the passage of the cerebrospinal fluid from the ventricles into the subarachnoid space being obliterated. The meningeal syndrome, the most frequent complication due to lumbar puncture, developed in 65 per cent of the cases in which there were complications. Either it was in an abortive form with headache, cervical and sacral pain, nausea and vomiting, or there were evident typical meningeal symptoms, such as rigidity of the neck and Brudzinsky and Kernig signs. The lumbar punctures were followed by complications more often in adults than in children and more often when the puncture was carried out with the patient sitting than lying down.

#### Withdrawal of Jews from the Medical Profession

The Association of Physicians in Poland, since introducing in its statutes the Aryan paragraph previously reported in *THE JOURNAL*, has taken strong action to withdraw Jews from the medical profession. A deputation of the association appealed to the medical departments of all Polish universities not to admit Jews. The demands were partially followed by the universities. The percentage of Jewish candidates admitted lately to the medical departments in all Poland amounts only to 37.

### Marriages

WILLIAM RUSSELL FUNDERBURG New Carlisle Ohio, to Miss Anna Marie Couch of Orlando Fla. Sept 10 1938

MARVIN SMITH CASHION, Mooresville N C to DR DOLORES ISABEL MENDEZ of San Juan, P R, Nov 12 1938

JOSEPH RUSSELL COOK, Huntington W Va, to Miss Sue MacIn Burr of Blacksburg Va. Nov 23 1938

ARTHUR WILLIAMS ROBISHAW Elyria Ohio, to Miss Ora Elizabeth Champion of Bellevue, Oct 26, 1938

LAWRENCE EDWARD FOULKE, Washington, Ill., to Miss Lois Merle White at La Grange, Ill., Oct 25 1938

SUMNER WILDMON BROWN Donalds S C to Miss Mary Robertson of Gold Hill, Ala. Aug 24 1938

PATRICK JOSEPH FAHEY Des Plaines Ill to Miss Theresa Noon of Onaway, Mich., Sept 10 1938

THOMAS JOHNCEY FLOYD JR, Jersey City, N J, to Miss Juliet Jordan of Hartsboro Ala, recently

HENRY CLAY SMITH, Boyce Va to Mrs Mary Martin Singer of Clarke County, Oct 25 1938

THOMAS F FARFEL, Prairie du Chien, Wis, to Miss Juanita Heberer of St Louis Nov 16 1938

JOE EDWARD FRID COLUMBIA S C, to Miss Katherine Werts of Prosperity, Nov 10, 1938

GEORGE COOPER JR to Miss Juliet Foster Paine, both of Charlottesville, Va., Nov 24, 1938

JOHN WESLEY RICE, Sturgis Mich, to Miss Edythe Ball of Montrose, Ill, in November 1938

ALVIN H JACOBS, Pittsburgh, to Miss Opal Sedalia Wilson of Wendell N C, Nov 5 1938

HERBERT FOX Philadelphia to Miss Mary Harlan Rhoads of Moorestown, N J Dec 3, 1938

EDGAR CLAY HARPER to Mrs Dorothy Seaman Albright both of Richmond Va, Oct 15 1938

WILLIAM FELIX FEAR Westmont, N J, to Miss Rosahe M Reilly of Berlin Nov 24, 1938

WILLIAM ABEL FRITZ to Miss Elaine Morell Maness both of Hickory, N C, Nov 24 1938

JAMES LUTHER FULLER to Miss Lillian Mae Abbott both of West Point Miss recently

#### CORRECTION

The date of the marriage of Dr Gustave Freeman published in *THE JOURNAL* January 14 page 165 should have been Oct 29, 1938 instead of Dec 29 1938

### Deaths

Alfred A Chapman of Sweetwater, Texas, University of Texas School of Medicine, Galveston, 1904, past president of the Nolan-Fisher Counties Medical Society, served during the World War, for many years member and president of the school board, on the staff of the Sweetwater Hospital, formerly health officer, at one time member of the board of trustees of the Southwestern University, Georgetown, aged 64, died, Oct 7, 1938, of Hodgkin's disease

John Champlin of Westerly, R I University of the City of New York Medical Department 1886, member of the House of Delegates 1902-1904 1906-1909 and in 1912, past president of the Washington County Medical Society, formerly chairman of the state board of public welfare, on the staffs of the Westerly (R I) Hospital and the Rhode Island Hospital, Providence, aged 75, died, Nov 27, 1938, of coronary thrombosis

Charles Serpa Neves, Montclair, N J, Harvard University Medical School, Boston, 1913, member of the Medical Society of New Jersey school physician, served during the World War, at various times on the staffs of St Vincent's Hospital, Community Hospital and the Mountainside Hospital, Montclair and the Essex County Hospital for Contagious Diseases, Belleville, aged 51 died, Nov 4, 1938, of coronary occlusion

Robert Miller Cochrane of Surg, Lieut Commander U S Navy, Dahlgren, Va, University of Pennsylvania School of Medicine, Philadelphia, 1917, served during the World War, entered the Navy in 1921 served as urologist at the Naval hospitals at New York, Boston and Philadelphia and in the Nicaraguan expedition, aged 46, died, Nov 30, 1938, of coronary occlusion

Paul Rutherford Macfadyen, Concord, N C, University College of Medicine, Richmond 1901, member of the Medical Society of the State of North Carolina, fellow of the American College of Surgeons, on the staff of the Cabarrus County Hospital, formerly physician in charge of the Concord Hospital, aged 64, died, Nov 26, 1938, of acute hepatitis and cirrhosis of the liver

Jose Antonio Lopez y Antongiorgi of San Juan, P R Syracuse University College of Medicine 1904 member of the Medical Society of the State of New York, at one time professor of surgery at the New York Polyclinic Medical School and Hospital New York, aged 57 died, Nov 19, 1938, in the New York Polyclinic Hospital, following an appendectomy

William Henry Schwingel of Aurora, Ill Rush Medical College Chicago, 1905 past president of the Kane County Medical Society, fellow of the American College of Surgeons, on the staff of St Joseph Mercy Hospital, Copley Hospital and St Charles Hospital, aged 67, died Nov 7 1938 of injuries received in an automobile accident near Osceola, Wis

Theodore Alpheus Felch, Ishpeming Mich, Detroit Medical College, 1874, member of the Michigan State Medical Society, member of the House of Delegates of the American Medical Association in 1903 and in 1909, formerly mayor of Ishpeming and health officer aged 91, died, Nov 21, 1938, of arteriosclerosis and myocarditis

Andrew Clinton Harrison, Charleston, Miss, Memphis (Tenn) Hospital Medical College, 1899 member of the Mississippi State Medical Association, aged 72, died Nov 14, 1938 in the Methodist Hospital, Memphis, Tenn, of hypertrophy of the prostate, bacterial endocarditis and brain abscess

Hugh H Haralson, Vicksburg Miss, University of Louisiana Medical Department New Orleans, 1883 member past president and secretary of the Mississippi State Medical Association formerly member of the state board of health county jail physician aged 84, died Nov 18 1938

Frederick Earl Diemer, Denver, University Medical College of Kansas City, Mo 1908, member of the Colorado State Medical Society served during the World War aged 53 died, Nov 29, 1938 in the Fitzsimons General Hospital of arteriosclerosis hypertension and cerebral hemorrhage

Nathan Powell Graham of Indianapolis Medical College of Ohio Cincinnati 1899 at one time assistant in medicine, Indiana University School of Medicine on the staff of St Vincent's Hospital served during the World War, aged 62, died Nov 27 1938, of cerebral hemorrhage

Samuel Adams of Jersey City N J, New York Homeopathic Medical College and Hospital New York 1900 police surgeon and school physician aged 77, died Nov 16 1938 in the Fifth Avenue Hospital New York, of chronic myocarditis, carcinoma of the stomach and cholelithiasis

**David Handmacher**, Cleveland, Cleveland Homeopathic Medical College, 1898, Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1904, aged 83, died, Nov. 28, 1938, of arteriosclerosis, pyelitis and hypertrophy of the prostate.

**Albert Andrew Crabbe** ♂ Traer, Iowa, Keokuk Medical College, College of Physicians and Surgeons 1900, past president and secretary of the Tama County Medical Society, for several years health officer, aged 67, died suddenly, Nov. 29, 1938, of coronary occlusion.

**William Lincoln Carden**, Andersonville, Tenn. (licensed in Tennessee in 1889), member of the Tennessee State Medical Association, past president of the Anderson County Medical Society, aged 73, died, Nov. 3, 1938, in St. Mary's Hospital, Knoxville, of cholecystitis.

**George Bales Breedlove**, Martinsville, Ind., University of Tennessee Medical Department, Nashville 1900, served during the World War, formerly county health officer, aged 72, died Nov. 10, 1938, of coronary and cerebral thrombosis, myocarditis and hypertension.

**Samuel L. Brister**, Greenwood Miss., Memphis (Tenn.) Hospital Medical College, 1888, for many years member of the board of trustees of the city schools, on the staff of the Greenwood-Leflore Hospital, aged 74, died, Nov. 10, 1938, of carcinoma of the prostate.

**Edward Ellsworth Blythe**, Riverside Iowa State University of Iowa College of Medicine, Iowa City, 1904, member of the Iowa State Medical Society, aged 64, died Nov. 5, 1938, of lobar pneumonia, diabetes mellitus and hypertrophy of the aorta.

**Henry Muncie Lyda**, Grisco City, Ala., Memphis (Tenn.) Hospital Medical College, 1905, member of the Medical Association of the State of Alabama, veteran of the Spanish American War, aged 70, died, Nov. 4, 1938, of cardiorenal vascular disease.

**Aristides Tillou Barbin**, Marksville, La., University of Nashville (Tenn.) Medical Department 1901, member of the Louisiana State Medical Society, parish coroner and formerly mayor, aged 61, died, Nov. 5, 1938, of multiple abscesses of the liver.

**John Henry Andrews**, Hyannis, Mass., Harvard University Medical School, Boston, 1902, member of the Massachusetts Medical Society, for many years on the staff of the Cape Cod Hospital, aged 62, died, Nov. 22, 1938, of cerebral hemorrhage.

**Augustus Melville Harrelson**, Stringer, Miss., University of Tennessee Medical Department, Nashville Tenn., 1892, served during the World War, aged 73, died, Nov. 27, 1938, in Bay Springs, of cerebral hemorrhage and cirrhosis of the liver.

**Arthur Albert Kahala**, Crookston, Minn., Minneapolis College of Physicians and Surgeons, 1902, member of the Minnesota State Medical Association, fellow of the American College of Surgeons, aged 61, died, Nov. 19, 1938, of chronic myocarditis.

**Willis Joseph Colbert** ♂ Youngstown, Ohio, Georgetown University School of Medicine, Washington, D. C. 1918, on the staff of St. Elizabeth's Hospital, aged 44, died, Nov. 28, 1938, of acute coronary occlusion and chronic myocarditis.

**Porter Barry Lennox**, Washington, D. C., Howard University College of Medicine, Washington, 1917, assistant professor of pathology at his alma mater, aged 50, died, Nov. 9, 1938, of peritonitis abscess and acute nephritis.

**John Tugaw Legier** ♂ Carmi, Ill., Bellevue Hospital Medical College, New York, 1891, past president of the White County Medical Society, on the staff of the Carmi Hospital, aged 71, died, Nov. 7, 1938, of nephritis.

**Andrew Otteraaen**, Wenatchee, Wash., Loyola University School of Medicine, Chicago, 1917, member of the Washington State Medical Association, county health officer, aged 54, died, Oct. 30, 1938, of coronary thrombosis.

**James Carlisle Dodson**, Richelieu, Ky., University of Louisville Medical Department 1912, member of the Kentucky State Medical Association, aged 51, died, Nov. 1, 1938, of acute infectious pyelitis and hypertension.

**William Austin Mills**, Hohokus, N. J., University of Vermont College of Medicine, Burlington 1881, veteran of the Spanish-American and World Wars, aged 82, died, Nov. 30, 1938, of cerebral hemorrhage.

**William Wilson Houston**, Good Hope, Ill., Keokuk (Iowa) Medical College, College of Physicians and Surgeons 1901, aged 61, died Nov. 8, 1938, in the Marietta Phelps Hospital, Macomb, of chronic nephritis.

**Norman Walter File** ♂ Lynchburg, Va., Baltimore Medical College 1908, served during the World War, aged 34, on the staff of the Virginia Baptist Hospital, where he died, Nov. 4, 1938, of cerebral hemorrhage.

**Willis London Franklin**, Ky., Vanderbilt University School of Medicine Nashville Tenn., 1888, member of the Kentucky State Medical Association, aged 74, died Nov. 6, 1938, of hypertension and myocarditis.

**Joseph Alonzo Lockett**, Dell, Ark., University of Tennessee College of Medicine, Memphis, 1916, member of the Arkansas Medical Society, aged 60, was killed, Nov. 22, 1938, in an automobile accident.

**John A. M. Nolen**, Alexander City, Ala., Medical College of Alabama Mobile, 1904, member of the Medical Association of the State of Alabama, aged 61, died, Nov. 8, 1938, of cerebral hemorrhage.

**William H. Kalbfleisch**, Balgonie, Sask. Canada, Western University Faculty of Medicine, London Ont. 1898, for many years mayor, aged 70, died recently, of a skull fracture received in a fall downstairs.

**Marcenus C. Mason**, Rochester, N. Y., University of Buffalo School of Medicine 1888, died Oct. 26, 1938, of arteriosclerotic heart disease, cerebral hemorrhage and benign prostatic hypertrophy.

**Samuel Solomon Danziger**, Columbus, Ohio, Detroit College of Medicine and Surgery 1916, served during the World War, aged 43, died Nov. 28, 1938, of acute cardiac decompensation.

**William Pomeroy Biggart**, Lancaster, S. C., Medical College of the State of South Carolina Charleston 1923, aged 40, died Oct. 22, 1938, in the Veterans Administration Facility, Columbia.

**Eugene J. Brown**, Stanford, Ky., University of Louisville Medical Department 1891, member of the Kentucky State Medical Association, aged 71, died, Nov. 11, 1938, of cerebral hemorrhage.

**Eugene Aaron Hawley**, Terrell, Texas, Rush Medical College, Chicago 1896, member of the Arkansas Medical Society, aged 62, died, Nov. 4, 1938, of pneumonia and heart disease.

**J. Russell Mosier**, Harfield, Pa., University of Maryland School of Medicine, Baltimore, 1883, member of the Medical Society of the State of Pennsylvania, aged 83, died, Oct. 14, 1938.

**Callender L. Johnson** ♂ Dallas, Texas, Howard University College of Medicine, Washington, D. C. 1897, aged 70, died, Nov. 14, 1938, of coronary occlusion, hypertension and nephritis.

**Alonzo Allen Fuson**, Summum, Ill., St. Louis University School of Medicine 1912, on the staff of the Graham Hospital, Canton, aged 55, died suddenly, Nov. 18, 1938, of heart disease.

**Peter John Fisher Houston**, Toronto Ont. Canada, University of Toronto Faculty of Medicine 1904, on the staff of the Toronto East General Hospital, aged 60, died, Nov. 7, 1938.

**John Thomas Craddock** ♂ Mackinaw City, Mich., Ohio State University College of Medicine, Columbus 1925, aged 46, died Nov. 12, 1938, of coronary thrombosis and hypertension.

## Bureau of Investigation

### RX MEDICINAL SPIRITS

#### The Peculiar Claims for a "Nonintoxicating" Whisky

For about a year a group using the trade style "R<sub>x</sub> Medicinal Spirits," 2100-2120 South Morgan Street, Chicago, has been promoting to physicians a whisky named "Prescription Brand." Apparently prior or coincidental to this, R<sub>x</sub> Medicinal Spirits of Peoria, Ill., was distributing a similar product called "RMS Private Formula." One of the advertising pieces for the latter product, distributed with the compliments of the manufacturer of the former, was entitled "Authentic Abstracts on Alcohol and Whiskey." It contains reprints of what appear to be photostatic copies of articles appearing in various scientific journals. Inquiry of the editors of these journals indicates that, at least in most cases, permission was not obtained to reproduce this material. Since some of the articles were taken from *THE JOURNAL*, the firm was asked to discontinue the use of the material, which it claims it has done.

Although this whisky is labeled "94 proof" and carries the state of Illinois tax stamp for one pint of alcoholic liquor, it is claimed that it is practically free from poisonous congeners which the United States Pharmacopeia does not even recognize. An advertising folder includes a copy of the U S P description of whisky, and to this description the manufacturers have added notations that the assays are 45 years old and that no mention is made of fusel oil, furfural and aldehyde, all of which are marked poison.

The method of purification is described in a form letter as follows:

Our manufacturing technique begins where the manufacturer of beverage whisky stops. For example, we take a 2 to 4 year old whiskey that is supposed to be finished and ready for bottling by the beverage manufacturer and we then by means of complete fractionation and absorption remove the poisonous congeners. This is all done without disturbing the mellowness palatability alcoholic content or optic value. After this whiskey has been washed and cleansed ready for consumption it has a much milder taste and there is no harsh after reaction.

The claim of the manufacturer and distributor is that the toxic, habit-forming narcotics and hypnotics have been reduced to a minimum in this brand of whisky. The firm states in one of its form-letters that:

Used as a prophylactic it will prohibit the possibility of ever becoming an inebriate. Used as a remedial whiskey in chronic alcoholism it tends to make a moderate and sane drinker. The physiological and psychological results are automatic because the patient is not denied his liquor and in the absence of narcotics the quantity imbibed decreases.

No doubt such a treatment would be acceptable to the drunkard. It could never, by the greatest stretch of the imagination, be considered a cure for chronic alcoholism. The suggestion appears as a pernicious piece of folderol.

According to the manufacturers, they have been able to reduce the furfural, the aldehyde and "amyl" and "iso-amyl" (sic). That these ingredients may be poisonous is not denied. That they are any more poisonous in the quantity in which they may occur in U S P whisky than the whisky itself, or the alcohol content therein, is most certainly not at all evident, in spite of the reports from the literature entitled "Authentic Abstracts."

During Prohibition some drinkers partook of grain alcohol, diluted and flavored, and even straight, it seemed to be a satisfactory product for producing the euphoria and the inebriation desired by those addicted to alcohol. This is not surprising, in view of the following quotation from Sollmann's "A Manual of Pharmacology," 1936 (Philadelphia, W B Saunders Company):

The impression prevails widely that the impurities [higher alcohols and ethers and esters formed from these and called collectively fusel oil] add materially to the harmfulness of the liquors but practically all scientific investigations have confirmed the conclusion that there is practically no objectively discoverable difference in action between any of the potable spirits ranging from the rawest to the most delicate. They are all about equally and quite insignificantly more irritant and more toxic than pure ethyl alcohol. The differences are purely in the flavor and its psychic suggestion. This has been the practically uniform result of all critical investigations and could be deduced from the nature and quantity of the impurities.

Some of the authentic abstracts would seem to refute some of these statements, others, however, support it.

**Landon Armstrong Colquitt** ☉ Waskom, Texas, University of Texas School of Medicine, Galveston, 1922, aged 42, was killed Nov 22, 1938, in an automobile accident.

**James Augustus Johnson**, Philadelphia Howard University College of Medicine Washington, D C, 1906, aged 57, died, Oct 27, 1938, of uremia and chronic nephritis.

**Garvyn Priestly Hicks**, Bruceton, Tenn., University of Nashville Medical Department, 1905, aged 58, died, Nov 23, 1938, in Lake Worth, Fla., of coronary thrombosis.

**Grant Giles**, Bloomfield Iowa, Keokuk Medical College, 1898, aged 70, died, Nov 26, 1938, of carcinoma of the prostate and hypostatic pneumonia.

**S MacDonald**, Collinsville, Miss Mississippi Medical College Meridian, 1909, aged 57 died Nov 18 1938, of injuries received when a horse he was riding fell on him.

**Verden Giddings Slater**, San Bernardino Calif., Stanford University School of Medicine, San Francisco, 1932, aged 33, died, Oct 29, 1938, of pulmonary tuberculosis.

**M Samuel Alexander**, Goose Creek, Texas, Memphis (Tenn.) Hospital Medical College, 1912, health officer, aged 68, died, Nov 8 1938, of diabetes mellitus.

**Howard Nelson Leeds**, Cincinnati, Medical College of Ohio, Cincinnati, 1907, served during the World War, aged 55, died, Nov 10, 1938, of carcinoma of the rectum.

**Charles Wainwright Birnie**, Sumter, S C., University of Pennsylvania Department of Medicine, Philadelphia, 1898, aged 64, died, Nov 22 1938, of a spinal tumor.

**Charles Gordon Brown**, Spokane Wash Long Island College Hospital Brooklyn, 1876 aged 90, died, Nov 8, 1938, in St Maries, Idaho, of coronary thrombosis.

**Thomas Duncan**, Fleta Ala Medical College of Alabama, Mobile, 1892, aged 72, died, Nov 17, 1938, in a hospital at Montgomery, of gangrene of the intestine.

**Arthur O Jones**, Greensboro N C (licensed in North Carolina in 1890), aged 71, died Nov 25, 1938, in the Piedmont Memorial Hospital of bronchopneumonia.

**Edwin J Lowell Robinson**, San Diego, Calif., Homeopathic Hospital College, Cleveland, 1883, aged 78, died, Oct 25 1938, of ulceration of the stomach.

**Jess Henry Moeller**, Maddock N D, Kongelige Frederiks Universitet Medisinske Fakultet, Oslo, Norway, 1892 aged 73, died, Nov 23, 1938, of heart disease.

**Rowland Francis Altree**, Tampa Fla., Medical College of Alabama, Mobile, 1899, aged 66, died, Oct 22, 1938, of chronic myocarditis and nephritis.

**Paul Barnabus Bauer** ☉ White Hall Ill., University of Illinois College of Medicine, Chicago, 1934, aged 36, died, Nov 15, 1938, of brain tumor.

**Julius K Elms**, Lincoln Neb., Chicago Homeopathic Medical College 1879 aged 88 died, Oct 22 1938, of chronic nephritis and arteriosclerosis.

**Robert Wilson Cook**, Adolphus Ky Vanderbilt University School of Medicine Nashville, Tenn., 1894, aged 78 died Nov 16, 1938, of angina pectoris.

**Walter B House**, Saugatuck Mich., Chicago Homeopathic Medical College, 1885, aged 81, died, Nov 30 1938, of cerebral hemorrhage.

**William Hyndman**, Jackson Mich Detroit Medical College 1877, aged 87 died Nov 28 1938, of arteriosclerosis and cerebral hemorrhage.

**Fred Leslie Redman**, Corinna Maine, Medical School of Maine, Portland 1893, aged 79, died Oct 30, 1938 of hemorrhage of the stomach.

**Edward Joachim Couillard** ☉ Northbridge Mass Baltimore Medical College, 1909, aged 57, died, Oct 8, 1938, of cerebral hemorrhage.

**John C Bryan**, Chicago, Rush Medical College Chicago, 1877, aged 88, died, Nov 4, 1938 of chronic myocarditis and arteriosclerosis.

**Frank E Burgess**, Dexter Maine (licensed by years of practice), aged 81, died, Oct 23, 1938, of valvular heart disease.

**Selmon A Casady**, Shenandoah Iowa Keokuk Medical College 1891, aged 87, died Nov 15 1938, of coronary sclerosis.

In the promotion of this whisky in the treatment of alcoholism, the firm is using a case history which reads as follows:

The patient, whose clinical course I am about to relate was referred to me by Dr T on June 25 1937. J M, a professional man from southern Illinois aged 37 was first seen by Dr T on April 7 1935 at which time he was admitted to the St Francis Hospital for the treatment of Acute Alcoholism. Since that date until the present admission he has been in and out of the Hospital at least once every month for treatment of the same condition. On May 31 1935 he developed a toxic myocarditis as evidenced by the definite tachycardia etc. During the latter part of December 1935 for the first time he became very unruly and vicious. Also at this time there occurred a rupture of some esophageal varices. Since December 1935 every time that he would go on a drinking bout he would become very vicious and wild—throwing furniture about and even grabbing small children by the nape of the neck and throwing them around.

On this last admission to the Hospital he entered on June 21 1937 and from that date until June 25th the treatment of his condition consisted of 5% glucose solution intravenously hydrothermy sodium bromide 10 grains as needed and whiskey one ounce every four hours. During this time he would get up and about and come out into the corridors bother visitors, and loudly insisted on using the desk telephone—thus presenting quite a nursing problem. His pulse rate ranged well over a hundred—the highest being 132.

The morning of June 25 1937 the patient was started on Private Formula Whiskey and all other medications were stopped. He was allowed to consume as much of this whiskey as he desired. That night he slept well without the aid of any sedatives or hypnotics much to the surprise of the night supervisor. The following morning he awoke without any headache or hangover and ate some breakfast—the most he had eaten since his admission. The next two days June 26 and 27 he was allowed again as much Private Formula Whiskey as he wished to drink. He began to eat something, at mealtimes and was content to stay in his room and sleep. His pulse rate ranged in the 90's—the highest being 100 despite the fact that he consumed approximately six and one half pints during these three days. On the morning of June 28th he stated that he did not want any more whiskey and that all he wanted was something to quiet his nerves. That noon he had an emesis of bright red blood but the following morning (June 29) he felt much better and was so docile that his sister thought he was worse since she had always seen him wild and unruly. He was discharged from the Hospital on that date.

The use of 6½ pints of whiskey over a three day period should satisfy any but the exceptional drunkard, it is not at all surprising that he had no desire on the third day for anything except something to "quiet his nerves." Since this patient was discharged at this time and further data concerning him are not given, the evidence of the effect of this preparation on his habits is completely inadequate. In spite of this, the doctor on whose stationery this case is mimeographed summarizes as follows:

From my experience with this patient who no doubt was a heavy drinker for at least three years to our knowledge the use of Private Formula Whiskey was of definite therapeutic value. To summarize what in my opinion are the important facts:

- 1 There were no prohibitions put on the one and only thing that the patient wanted and there were no prohibitions placed on the amount that he could drink. As a result his wholehearted cooperation and confidence were gained and certainly these are necessary in treating such a patient.

- 2 He lost the taste for whiskey and could not be persuaded to take another drop. In fact the patient was quite pleased about it and even told the nurses that they should never bring any more whiskey into his room.

- 3 He suffered no headache or hang over and his pulse rate was not alarmingly increased.

- 4 No sedatives or hypnotics were necessary for sleeping or restlessness during the administration of Private Formula Whiskey.

- 5 He became a gentleman instead of being wild and unruly.

At this writing I have observed in consultation the use of this Whiskey in three other patients and the results obtained have been similar. The clinical records are not available at present, so I am unable to report them. However, one of these patients was on the border line of Delirium Tremens and the use of Private Formula Whiskey controlled the condition very remarkably much to the amazement of the Attending Physician. I do not think that definite scientific conclusions should be made from such a small number of cases but certainly they reasonably demonstrate the efficacy of Private Formula Whiskey as a positive therapeutic aid in the treatment of Chronic Alcoholism.

Everything under the sun has been used in the attempt to cure drunkenness, inebriation and chronic alcoholism. The idea of using whiskey in unlimited quantities, however, whether or not it contains the various impurities which this manufacturer claims to have reduced, is preposterous. As far as we know, the only way to "fix up" whiskey so that it does not produce drunkenness, inebriation and eventually habit in some individuals who become addicted to it is to remove the alcohol—and then it isn't whiskey.

While this method of treating alcoholism may become popular with alcoholics, the continued use of this product will not lead to either sobriety or abstinence. The promotion of this product in the complete absence of satisfactory evidence is a triumph of ingenuity and imagination but it is certainly not scientific.

### AN UNFORTUNATE SITUATION IN THE FIELD OF BACTERIAL CHEMOTHERAPY

To the Editor.—In spite of the hopeful outlook in the field of bacterial chemotherapy, certain tendencies which have become obvious in the past three years should cause grave concern to serious and thoughtful students of this subject. It may be opportune to call attention to several of these in the hope that all concerned may attempt to combat these pernicious tendencies which threaten to delay advance in a field of so much importance to the health of mankind. The meaningless therapeutic experiments on mice which are constantly being published by investigators of presumably good scientific standing, the administration to human beings of chemical compounds before any detailed information of the chemical structure and properties of such compounds has been made available to medical investigators or practicing physicians, and the use of drugs in sick human beings before adequate toxicologic and pharmacologic investigation on animals is available can only impede true progress and lead to unnecessary human suffering and death.

A new and promising field is always immediately invaded by workers from other fields. Results must be obtained over night and reputations made (or blasted) in a month. Instead of the time-honored slow and laborious method of reaching conclusions some short cut method is adopted without the investigator (we hope so at first) being aware that the experiment cannot yield an answer to the question at issue. Almost every week one sees articles which describe the attempts of an investigator to compare either two or more methods of administering the same drug or two or more drugs administered by the same method as to their therapeutic efficiency on some experimental bacterial infections of mice but the investigator uses such a limited number of animals that his conclusions are unjustified. The experiments cause other workers a loss of time and effort and frequently are taken over into the clinic with unsatisfactory or even disastrous results. Many of the investigators who have entered this field have made no attempt to evaluate the significance of their figures or to analyze and test their meaning by even an elementary statistical technique.

To decide if a new compound is active as an antibacterial agent in mice, only a few animals are necessary provided the untreated controls all invariably die in a few days. Prolongation of life or survival of some of the treated animals gives an unequivocal answer to the question. But this answer is only a qualitative one and with a few animals no statement can be made as to the relative efficiency of two drugs or two different methods of administering the same drug. The number of mice which it is necessary to use to answer such questions will depend on the magnitude of the difference. Thus, for example, when two groups of six mice are used and one mouse in one group and five in the other survive, the probabilities of such a difference being due to chance are about 1 in 10. With ten mice in each group the death or survival of three in one group and seven in the other is not statistically significant, since divergences as extreme as this are likely to occur by chance about one in six times.

If investigators refuse to recognize the simplest statistical principles I suggest that the editors of reputable journals refuse to accept the manuscripts of such investigators and inform them in no uncertain terms of the inadequacy of their results. The difficulties which are involved in accurately assessing two procedures of treatment or two different drugs are many but those which are due to an insufficient number of animals should not be countenanced.

The identity and purity of a chemical compound to be used as a drug and administered to human beings have not been accorded the attention they deserve from the physicians who order the administration of the drug. Recently a compound stated to be 2-sulfamimidopyridine was found to be extremely effective in pneumococcal infections in mice. Quickly this compound was tried in pneumonia in man with apparent beneficial results. The drug is still under trial and is being administered to thousands of sick persons, but as yet no description of the substance has been published. The proof of its chemical structure, analyses for purity and chemical properties are withheld from investigators and physicians who are using the drug. Obviously this is due to the patent situation with regard to new drugs.

Another serious situation is the fact that new drugs are introduced into human therapy before an adequate toxicologic study of their properties has been performed on animals. The need for this appears obvious but there has been a tendency in the clinical literature on sulfamidamide derivatives to take the point of view that toxicity experiments carried out on animals are of little use in determining the toxicity of this group of drugs for the human being. These statements are based on the fact that many toxic reactions are seen in patients when the drug is administered which could not be predicted from animal experimentation. This is no new thing to pharmacologists but has been known almost since the birth of scientific pharmacology. I know of no case in which the toxicology and pharmacology of a new drug have been satisfactorily worked out even in a preliminary way by a competent pharmacologist and the drug found to be dangerous for clinical use that clinical trial has reversed this opinion. I need only refer to the recent instance, which is fresh in the minds of all physicians, of the wholesale slaughter of patients by the use of a solution of sulfamidamide dissolved in diethylene glycol. A few simple animal experiments could have avoided this disaster.

One could quote hundreds of instances in which chemical compounds possessing some desirable therapeutic effect have been discarded for clinical trial because preliminary animal experiments indicated that the drug would be highly dangerous and too toxic for human use. The reverse of this proposition is, however, not true. Even when a drug has been subjected to a complete and adequate pharmacologic investigation on several species of animals and found to be relatively nontoxic it is frequently found that such a drug may show unexpected toxic reactions in diseased human beings. The reason for this difference is, I believe, threefold. With the higher development of man, it is to be expected that many drugs will prove more toxic for man than for the lower animals. Second there is every reason to believe that one will find more hypersensitive individuals to any given drug among diseased human beings than among a group of laboratory animals. Indeed it is quite probable that many drugs are more toxic to the diseased than to the normal individual. Third, it is known that idiosyncrasies occur in normal and diseased human beings and so far this has not been predicted by animal experimentation. In spite of this adequate pharmacologic investigation on animals is necessary.

Should more argument be needed for the importance of the proper support of pharmacology in our medical schools it is certainly furnished by the recent history of bacterial chemotherapy. Owing to the almost miraculous therapeutic results which have been obtained with the sulfonamide group of drugs in infectious disease it is certain that stupid and unscientific use of these and similar new drugs will be attempted in the future. A recognition of the value of pharmacology in connection with the development of a drug as a chemotherapeutic agent is essential, if disastrous results are to be avoided.

E. K. MARSHALL, JR., PH.D., M.D., Baltimore

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON LOCAL MATTERS WILL NOT BE NOTICED. LETTERS MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### TRICK AP ONSET OF MENSTRUAL PERIOD

*To the Editor:* A white married woman aged 36 had both tubes, the right ovary and the appendix removed in March 1905 following rupture of an ectopic pregnancy. For about a year thereafter her menstrual periods were apparently normal with no dysmenorrhea. Then, for no apparent reason, she began having severe cramps at her periods and fever as high as 104.1, beginning an hour or two after the onset of the menses and lasting three or four hours subsiding as suddenly as it had arisen. Nausea and occasional vomiting and pain on the stomach are concomitant symptoms. There are no intermenstrual symptoms. Uterine size is normal and the patch tuberculin test is negative. Pelvic examination reveals an anteflexed uterus with normal ovaries. What could cause such a transitory high fever and what method of treatment should be used?

LEIGH PRATT BROWN, M.D., Redford, Ohio

*ANSWER:* It seems probable that this patient's symptoms and fever are due entirely to a pelvic disorder and not to exacerbations of some systemic disease (such as tuberculosis) during the catamenia. The first possibility that suggests itself is a uterine fistula which allows the escape of menstrual blood and detritus into the peritoneal cavity. Such a fistula might follow imperfect healing of the uterine canal after excision of the tubes. A uterine fistula would account for the fever (peritoneal reaction to free blood), endometriosis, which would be expected as a sequel to the fistula, would account for the dysmenorrhea, cervical atresia, or kinking of the cervical canal due to extreme flexion of the uterus would favor the passage of blood through the fistula. In studying this patient one would first make careful vaginal and rectal examinations with endometriosis in mind. The discovery of nodules in the cul-de-sac would be suggestive, and increase in the size and tenderness of these nodules at the time of menstruation would be strongly suggestive of endometriosis. The cervical canal should be sounded and should be well dilated if there is any evidence of blockage. A Rubin test would show any communication between the uterine and the peritoneal cavities. Should such a communication be found, it should be further studied by x-rays to try to determine whether a fistula or a short segment of tube is present. Utero-peritoneal fistulas should be closed as a prophylaxis against endometriosis. The fistula is easier to locate and excise if methylene blue solution is injected into the cervical canal under pressure immediately before or just after the abdomen is opened. Care should be taken to excise or destroy any endometrial transplant found, especially those in the isthmus tract (salpingitis isthmica nodosa) in the hope of relieving the dysmenorrhea. Every effort should be made to provide a free cervical passage for the menstrual flow. The cervix should be widely dilated and any extreme flexion of the uterus should be corrected. As presented, the history does not suggest simple pelvic inflammatory disease or periodic psychosis, but these possibilities cannot be ruled out from the data available.

### DEXTRINS IN DIET

*To the Editor:* Please give opinions pro and con on the use of dextrins for infants and adults. Has any work ever been advanced showing the harmfulness of dextrins? D. P. FINEBERG, M.D., Los Altos, Calif.

*ANSWER:* Dextrins are polysaccharides intermediate between starch and maltose. They are not fermented by most intestinal bacteria but they are readily converted into maltose through the action of enzymes normally present in the intestinal tract. Commercial dextrin is usually a mixture of various dextrins.

It is believed that the usefulness of dextrins in infant feeding can be attributed in part to the gradual formation of maltose which when hydrolyzed into dextrose, is absorbed. Hence when dextrins are fed there is not at any one time an excess of fermentable carbohydrate in the intestinal tract. The Council on Foods (J. AM. J. Hyg., May 29, 1914, p. 1890) has pointed out that the carbohydrate preparations used in the artificial feeding of infants can conveniently be divided into three groups: pure sugar, hydrolyzed starch preparations and mixtures. The dextrin of course can be obtained by the partial hydrolysis of starch. It is interesting to note that it was the consensus of the Council in the light of evidence available that the choice of a sugar for use in infant feeding is of relatively minor impor-

tance as compared with other problems of infant feeding, but in individual cases it might be desirable to select one sugar over another.

Administered in reasonable amounts, dextrin should have no toxic action for either infants or adults.

#### DERMATITIS FROM CORE\*

*To the Editor*—I have two cases of severe dermatitis in young healthy men truck drivers who recently required this condition following exposure to some form of chemical transported in bags which sifted down on them in their sleeping quarters in transit. The material is known to the commercial trade as core and is shipped and used regularly in foundries. The patients present a generalized dermatitis of the face and neck the parts exposed during sleep to the reaction of the chemical. No other portion of the body is involved either symptomatically or clinically. They state that the powder is fine and black and that it completely covered their faces and necks during the hours of sleep. No symptoms were experienced until after washing the face in the morning. At the present time they are complaining of intense burning of all exposed areas of the hands and face but the scalp. Can you advise me what chemical is commonly used by foundries which might produce this condition?

P. W. FLAGGE, M.D., High Point, N. C.

**ANSWER**—The term "core" is not sufficient to identify fully any particular commercial product. However, in foundry practice cores are commonly made up of sand, bound together by some adhesive material, and are made stable by baking. A number of binders are available including granular pitch. This core material may not consist entirely of granular pitch but instead may be mixed with finely ground bituminous coal called "sea coal." The "sea coal" may be regarded as an adulterant but it may serve a useful purpose in limiting the hardness of the core after contact with hot metal. Tars, dextrin and molasses are also used as core binders. Cores are sometimes washed with suspensions of graphite or plumbago. Mention in the query that the irritating substance to which exposure occurred was black prompts the belief that the particular core material was a powdered pitch, tar or asphalt with or without powdered bituminous coal. Any one of these three substances might produce a dermatitis, particularly when the exposure is to fine particles. If the assumptions in this reply are correct, no persistent effects may be expected and prompt recovery after the acute episode may be anticipated.

#### ESTROGENS AND HYPERTENSION

*To the Editor*—Three years ago following a series of administrations of estrogen (5,000 international units) for menopausal flushes the patient's blood pressure dropped from 190 to 140 and remained at the lower level. Since then I have treated eight other patients with estrogen and have noted the same drop in blood pressure. In some cases this lowered blood pressure persisted for more than a year after the treatment was terminated. I also purposely treated with estrogen a man aged 52 with malignant essential hypertension and a systolic blood pressure of 210. His blood pressure fell 30 points. The type and degree of the cardiovascular conditions in the patients varied. Some were of ten years duration and accompanied by considerable cardiac and kidney changes yet a systolic and diastolic drop was effected in every one of these cases. I attributed this effect to the 'suppressive' action of the estrogen on that part of the pituitary responsible for control of blood pressure. I would appreciate your comment.

M. D., New York.

**ANSWER**—The vasodepressor activities of estrogens have been repeatedly observed, although it is but recently that clinicians have had available relatively pure preparations of the various pituitary and ovarian fractions. In 1916 Culbertson (*Surg Gynec & Obst* 23:667 [Dec] 1916) suggested that the climacteric type of hypertension and vasospasticity might be due to associated secretory changes in the pituitary. Similar changes in thyroid and adrenal activity are also to be considered. There is also evidence that normal ovarian secretion has a vascular sedative action. Alvarez and Zimmermann (*Arch Int Med* 37:597 [May] 1926) pointed out that in young women with abnormal menstrual cycles the average arterial tension is found higher than in the normal. The type of hypertension associated with the menopause is of a spastic, variable character and is greatly affected by the emotions (Maranon, Gregorio, *The Climacteric*, edited by Carey Culbertson, translated by K. S. Stevens, St. Louis, C. V. Mosby Company, 1929). Similar "emotional hypertension" is frequently observed in patients with abnormal sexual appetites, especially among those with borderline nymphomania (Stieglitz, E. J. *Am J M Sc* 179:775 [June] 1930).

More recent studies (Liebhart, S. *Zentralbl f Gynak* 58:1896 [Aug 11] 1934) on the clinical administration of follicular extracts reveal that it is effective in hypertensive women entering the menopause. Its application to other forms of hypertension has been, on the whole, much less satisfactory.

It must be reemphasized that hypertensive arterial disease is due to many etiologic factors, that frequently there are several provoking factors superimposed in the same patient and that each and every case of the disease must be treated as an individual problem. The variable results recorded in the query illustrate this. That endocrine disturbances not infrequently are etiologic factors in hypertensive disease is true but in every instance by any means. With careful diagnostic analysis, it is possible to elicit many contributing or provoking etiologic factors in a series of hypertensive patients. Perhaps the analysis is the most important aspect of effective therapy. It must be anticipated that in many cases the therapeutic results from the administration of estrogen will be disappointing.

#### POLYGRAPH OR LIE DETECTORS

*To the Editor*—I should like to know where I can obtain a detector and literature concerning it. Are lie detectors for sale on the market?

M. D. Kenner

**ANSWER**—There is actually no 'lie detector' and the present status of this whole question is controversial. Much of the existing chaos is due to the fact that although the principles underlying this field of research, the translation of emotional reactions into physiologic terms, are usually identical, machines are being patented, exploited for the most part by nonmedical men and sold to operators interested either in psychology or in medicine. Yet this apparatus involves the most complicated forensic clinical principles and instruments of precision. Usually a brief period of instruction of two or more weeks or mailed directions are given by those selling the machines, with attempts by them to control all further work carried out by the operator. One inevitable result is that the majority of those operating lie detectors for the police departments and commercial firms have no knowledge of the lying principles and are using the method as a psychological third degree. Unfortunately, the same operators are giving instructions, advertising "lie detectors" and some of the leaders, besides exploiting machines, are pictured in current magazines advertising commercial products.

Before purchasing any apparatus or conducting any experiments, one should consult the following minimum references:

- Burrill H. E. *Legal Psychology* New York: Prentice Hall Inc. 1931.
- The author is professor of psychology at Ohio State University, Columbus, Ohio.
- Larson John A. in collaboration with Haney George W. and Keeler Leonarde. *Lying and Its Detection* University of Chicago Press. 1932. Includes twenty three pages of bibliography.
- Reichsmid Christian A. *The Psychology of Feeling and Emotion*, New York: McGraw Hill Book Company Inc. 1936. The author was formerly professor of psychology at University of Iowa.
- Goldstein Irving. *Trial Technique* Chicago: Callaghan & Co., 1931. pp. 13-19. The author is instructor in trial technique, Northwestern University School of Law.
- Marston William. *The Lie Detector Test* New York: Richard L. Smith 1938. Since this book contains sweeping statements the following reviews should be consulted also: Larson John A. *Legal Review* 23:451-453 (March) 1938. Inbau Fred. *Journal of Criminal Law and Criminology* 29:305 (July-Aug.) 1938.

The apparatuses at the present time being exploited as 'lie detectors' include:

The "Keeler Polygraph" patented by Leonarde Keeler, formerly of the Crime Detection Laboratory at Northwestern University, now taken over by the Chicago Police Department including the apparatus and personnel with the exception of Mr. Keeler. The machine is manufactured by the Western Electric and Mechanical Company Incorporated, Oakland, Cal. The price was formerly \$450. Recently there has been added a galvanometer.

The Lee Polygraph or "Berkeley Psychograph," Lee and Sons, 1909 Delaware Street, Berkeley, Calif., \$250. The apparatus is the simplest to operate and mostly approximates the principles and polygraph used by Larson from 1923 to 1927.

The Darrow photopolygraph \$1,000, manufactured by the Stoelting Company, Chicago. This is the most complete apparatus available for research purposes. Included are the respiratory changes, vasomotor and blood pressure changes as recorded in the modified Thomas Polygraph, Lee and Keeler polygraphs, the Luria tremographs and voice keys (The Behavior Research Photo-Polygraph, *Journal of General Psychology* 7:215, 1932). This is also described as Lie Detector (An Improved Lie Detector Darrow Photo Polygraph, *Police* 13:13 [April] 1935). However, complaints have been received that this apparatus is much too complicated for practical procedure. To this Darrow may add a continuous quantitative method of determining blood pressure.

The "Pathometer" A psychogalvanometer devised by Father Summers, recently deceased, of the department of psychology of Fordham University. A picture of this was printed in the *Saturday Evening Post* May 21, 1938, in connection with a commercial advertisement. The claims made for the apparatus which is in use at Fordham University and by the Michigan State Police Department have been strongly criticized by Marston in his book and in more detail by Jordan (*Evidence Admissibility of Deception, Journal of Criminal Law and Criminology* 29, No 2, 1938). Samuel Renshaw and Bernard Higley describe "An Improved Device for the Continuous Pneumatic Recording of Respiration and Changes in Blood Pressure" (*Journal of Psychology* 4 281, 1937).

Larson reports satisfactory experimental results from the usage of a modified Thomas polygraph made by Earl Bryant of California. He does not regard as satisfactory any of the apparatuses now on sale with implications that they are "lie detectors." He feels that the psychogalvanometric method alone has not as yet proved its efficacy in criminologic work.

Hoover's conservative impressions may be found in "Scientific Methods of Crime Detection in the Judicial Process."

#### PRURITUS ANI

To the Editor—A man aged 45 has had pruritus ani for fifteen years. His general physical examination and routine laboratory tests including the Wassermann test have all been negative. He has had some small internal hemorrhoids which have reacted satisfactorily to the injection of quinine and urea solution. The treatment of the pruritus has included roentgen therapy, injection of alcohol and nupercaine with benzyl alcohol in almond oil. An autogenous vaccine has been made from his stool and has been used with complete failure. Gentian violet solution made the condition worse and caused a stubborn eczema to develop. I advised that he has reached the stage where surgery (Ball operation) offers the only hope for success. Could you suggest anything less radical but affording some hope of cure?

A A SKEMP MD LaCrosse, Wis

ANSWER—A careful search should be made for a fungous infection of the skin which not infrequently occurs and which would respond to Whitfield's ointment. The injection of alcohol through multiple punctures about one-half inch apart, from 1 to 2 minims (0.06 to 0.12 cc) being injected in each puncture throughout the area of dermatitis at a level of about one-half inch below the skin has been just as effective as the Ball operation. One should also make sure that there are no infected crypts, that the patient has no diarrhea that he does not have a fermentative stool with frequent passage of gas, and that he does not take liquid petrolatum. It is highly important that nothing come in contact with the skin but moist detergents and that the skin be kept scrupulously clean with soap and water. The measures should be tried before further operation.

#### EXTRAVASATION OF ARSPHENAMINE—PRURITUS AFTER ARSPHENAMINE

To the Editor—Aug 11 1938 I gave a patient an intravenous injection of 0.6 Gm of nearsphenamine. Unfortunately owing to the patient's restlessness some of the solution entered the tissues around the elbow. At the present time there is a small hard red lump that at times is painful and itchy and annoys the patient. Can you suggest a procedure to relieve this condition? After the ninth injection the patient developed a generalized pruritus without any dermatitis. I am giving him intravenous injections of 10 per cent calcium gluconate as well as external applications of 0.25 per cent phenol in olive oil. Is this the proper procedure?

M D Connecticut.

ANSWER—Regarding the first question, further treatment is not required. Extravasation of one of the arspenamines produces a localized cellulitis which may be sufficiently intense to break down and suppurate. If this can be avoided, however, the condition is then self limited and will in time subside, although it may require several months for the subcutaneous scar tissue to be absorbed. After the acute stage is over, local treatment is useless and attempts at surgical intervention merely serve to make the situation worse.

With the meager information furnished, an accurate answer to the second question is more difficult. Generalized itching developing after an injection of an arspenamine product is usually a danger signal warning the physician that further treatment with an arspenamine must be given with the greatest caution and only after intravenous testing, in the manner described by H M Robinson (*Intravenous Testing in Post-arsphenamine Dermatitis South M J* 29 411 [April] 1936), has demonstrated tolerance to the drug to be employed. This type of itching however, is short lived seldom lasting more than from twenty-four to forty-eight hours unless it is followed by a generalized eruption. It does not require treatment.

#### SMALL DOSES OF INSULIN IN OTOLARYNGOLOGY

To the Editor—What information can you give me regarding the use of insulin in ear nose and throat disorders especially chronic otitis media?

HENRY H AMSDEN, MD Concord N H

ANSWER—D C Jarvis of Barre Vt, has written a good deal on the use of small doses of insulin in ear, nose and throat disorders. The basis on which he makes his recommendations is in part theoretical and in part his own clinical experience and that of a correspondence study group. One may, of course, not agree with theoretical considerations and still have to pay attention to the claims of experienced clinicians when these claims are based on careful study of patients. Knowledge gained this way is frequently discovered in later years to have a sound basis in fact even though the theory proposed may be found faulty. However, in this case much more confirmatory evidence is needed.

The best exposition on the use of small doses of insulin in ear, nose and throat practice is to be gained from the writings of Jarvis himself. A recent article entitled "Small Doses of Insulin in Otolaryngologic Practice. Clinical Experience of a Correspondence Study Group" appeared in the *Archives of Otolaryngology* in July 1937.

In general the proponents of the "oxygen metabolism theory" state that small doses of insulin are useful in common colds both for prophylaxis and for treatment. They have been found of value in excessive nasal secretion and in the treatment of nasal polyp and acute and chronic otitis media as well as in other conditions. The curative value of small doses of insulin in cases of chronic otitis media in which the usual methods of treatment have failed is attested by a number of competent observers. The usual dose is three units given subcutaneously daily with a lengthening of the interval as clinical improvement takes place. Eventually the insulin may be given no oftener than once a week and continued for months.

#### ANGINA PECTORIS IN PAINTER

To the Editor—A man who has worked fifteen years as an automobile painter presents a probable angina pectoris syndrome. Symptoms began three months ago and have progressively become more severe. An attack is usually brought on by physical exertion for example, while walking to work. Emotional incidents have also produced the same effect. It begins with a sick feeling in the lower part of the chest and afterward changes to a burning sensation in the same region ascending to the anterior part of the chest and radiating to the back and down both arms to the elbows being more severe on the left. He also presents a general muscular wasting beyond his increasing years. He is 48 years of age and is generally high strung and apprehensive. The blood pressure is 105 systolic 60 diastolic. For the last twelve years he has had many abscessed teeth and a few remaining lower ones are abscessed and decayed. The rest of his physical examination is essentially negative. Blood count reveals red blood corpuscles 5 380 000 white blood corpuscles 12 950, hemoglobin from 95 to 100 per cent (Tallqvist). The blood Wassermann reaction is negative. Urinalysis is negative. He has used many varieties of paint during the last fifteen years. In recent years he has been painting by the spray method. Some of the many used paints are Duco Deluxe (synthetic enamel) and aluminum paint. He has had little contact with lead paints. I would appreciate any information you may have that would explain the possibility or impossibility that paints as described might be the cause of this clinical picture.

BARNEY LIHW MD Vineland N J

ANSWER—Angina pectoris cannot be regarded as a characteristic occupational disease among painters although Gerbis (*Arch f Gewerbepath u Gewerbehyg* 7 421 1936) has described angina pectoris resulting from the inhalation of trichlorethylene in another industry. On the other hand, hand painting and spray painting in the absence of suitable protective devices must be reckoned as associated with far more exposures than most occupations. This is less true in the present decade than it was for periods twenty or thirty years ago. This betterment is due to the use of less toxic materials in paints in later years. Among old time painters, the degenerative diseases are highly prevalent and the onset of such degeneration is earlier than for workers in general.

The National Tuberculosis Association in 1934 reported a much higher frequency of heart disease as a cause of death among painters than for selected other trades and for all occupations. In a hundred thousand gainfully occupied men the death rate from heart disease for painters was 247.3 and for all occupations 174.4. The corresponding death rate from nephritis was 89 for painters against 57.6 for all occupations. Likewise deaths from cerebral hemorrhage were more frequent among painters than for all occupations.

In this instance the angina pectoris described probably is not the result of working with any particular substance common to the painters trade and possibly is unrelated to work in any respect as a direct cause. However it is undoubtedly true that this painter has been exposed in the course of many years of

painting work to a fair number of substances which might have exacted some toll from his body. The number of possible agents includes benzene, toluene, lead, arsenic chromates, naphthalene, aniline oil, paranitraniline, acetates, esters and ketones. The substances mentioned in the query, such as Duco, are perhaps less harmful than other substances in wide use were two or three decades earlier. It is quite impossible to attribute this condition to any particular material found in the printer's work, but it may be recognized that painting as a trade leads to some deleterious effect on life and well being.

#### INHALATION OF BLACK FLAG OR PYRETHRUM

*To the Editor*—A white woman aged 73 while spraying flies with black flag about six weeks ago inhaled some vapor of the spray and noticed immediately severe burning sensations in the nose throat and the pit of the epigastrium in the order given. Ever since then she has been complaining of these unpleasant sensations. She also has hypertension and noises in her ears. She has been treated for the hypertension and has improved as far as the head noises and circulation are concerned. An anemist found two weeks after her so called poisoning (I did not see her before that) has improved also. In spite of all types of antacid medication she still appears to suffer enormously. Inhalations of functure of benzoin give transient relief. X-ray examination does not show any abnormality except for a severe ptosis of the stomach. What is the composition of black flag? Are there any chemicals in its composition that might be injurious to a human being? If so what antidotes are desirable? If it is necessary to have the contents of this can of black flag analyzed where can I have it done and at what fee?

M D Vermont

**ANSWER**—In THE JOURNAL July 12 1930, page 111, a case of black flag dermatitis associated with some systemic involvement is described by Sulzberger and Weinberg. On chemical analysis the responsible insect powder showed the presence of pyrethrum. Pyrethrum insect powder is derived from the pulverizing of buds of certain varieties of chrysanthemums. The pyrethrum industry flourishes in Dalmatia, California and Japan, among other places. This powder contains an effective insecticidal agent, when used as such or the active principal may be chemically extracted. Many of the commoner household insect sprays represent an extract of pyrethrum with naphthalene, deodorized kerosene or related petroleum derivatives. At least in times past, chlorinated hydrocarbons have been utilized in the manufacture of some sprays.

Granting that pyrethrum is a severe local irritant it is surmised that in the instance cited the immediate discomfort following inhalation of vapor was chiefly due to the action of the leaching liquid, probably a naphthalene or naphthalene-like body. Such vapors may irritate the nose and throat, but it is most unlikely that hypertension, head noises or anemia may be traced to this casual inhalation of hydrocarbon vapors containing pyrethrum. Occasionally persons become sensitized to the constituents of spray insecticides and as long as any trace is present about the household may suffer from skin disorders or minor respiratory irritation or peculiar perversions of tastes and odors. Unless in the present instance this condition is perpetuated on an allergic basis, and if the full extent of exposure was that described in the query, it seems reasonable to dismiss this insecticide as the source of any prolonged or severe manifestations from any organic disease. The advanced age of 73 is significant and may be more important than external irritants.

There are no known antidotes, but in pyrethrum dermatitis removal from further exposure, together with palliative treatment, is usually efficacious. It would seem advisable first to ask the manufacturer if he will supply the exact composition.

#### HANDLEY OPERATION FOR CARCINOMA OF BREAST

*To the Editor*—Is there an operation known as Handley's used to extirpate the breast? Is it a proper procedure in cancer of the breast? Would you please describe it and the rationale of its performance? Are the pectoral muscles removed? In the instance I know of they were not.

THOMAS I O DRAIN M D Philadelphia

**ANSWER**—The Handley operation for carcinoma of the breast is the one described by Sampson Handley (Carcinoma of the Breast and Its Treatment, New York, Paul B Hoeber 1922, p 239, also Christopher's Textbook of Surgery, Philadelphia, W B Saunders Company, 1936, p 958). Auchincloss (Christopher's Textbook of Surgery) says of this incision that emphasis is placed on the necessity for putting the growth in the center of the incision not only from the standpoint of the skin, but because the specimen to be removed should be similar to a bi-convex lens with the tumor in the center. This means an extensive undermining of the subcutaneous tissue and fascia. The amount of skin to be removed as recommended by Handley is not as great as that recommended by Halsted. The incision might be criticized from the standpoint of not removing enough

skin. The remainder of the operation is just the same as the standard radical operation in which both pectoralis major and pectoralis minor muscles are removed. The term "Handley operation" simply refers to the skin incision of which there are many. The fourteen principal ones are described by Auchincloss.

#### FUMES FROM ELECTRIC ARC WELDING

*To the Editor*—A patient who does electric welding has a bad reaction to the toxicity of the fumes formed he thinks by the heat from the asbestos like covering of the welding "rods". The rods go under the trade name of Lincoln Rods.

S F MENGEL M D Schuylkill Haven Pa.

**ANSWER**—Little is actually known about the fumes which arise from the coatings of welding rods, since they are in practically all instances trade secrets as to exact composition. They have been reported to contain copper, nickel, bronze, sodium fluoride, phosphorus and arsenic. Probably the chief harmful gases produced are the oxides of nitrogen, which even in low concentration are capable of producing pulmonary edema.

#### GARLIC IN GASTROINTESTINAL DISEASES

*To the Editor*—I have a patient with colitis and understand that garlic is used as a treatment. Will you please give me what information you have?

GERRIT MARIS M D Hull Iowa

**ANSWER**—The use of garlic (*Allium sativum*) as a medicine as well as a condiment can be traced to earliest antiquity, and periodically it has been exploited for this or that condition. Some years ago the use of garlic had a revival first in France and later in England, and then proprietary preparations claimed to be derivatives of garlic were put on the market. Preparations of garlic have not been shown to be of value except perhaps as irritant expectorants with local action on the stomach. The medical profession of this country appears not to have been impressed with the reported value of garlic preparations. Its use in gastrointestinal disease, especially diarrhea, constipation and colitis, is related in isolated case reports and poorly controlled trials published in the German literature. Its greatest popularity was enjoyed ten years ago and since then this use of garlic has markedly waned.

#### TRAUMA OVER HEALED OSTEOMYELITIS

*To the Editor*—I am interested in knowing whether a contusion or bruise in the region of an old apparently healed osteomyelitis or old healed suppurative arthritis will cause development of an abscess in the overlying soft tissues. I have recently seen two cases where there has been such a flare up. One was the development of osteomyelitis of the metatarsal bone in a patient who had an old suppurative osteomyelitis in the same foot in an adjacent metatarsal several years previously which had apparently healed. The other was a flare up in the soft tissues overlying a latent or apparently healed suppurative arthritis of the hip. Any information on this matter would be appreciated.

M D Wisconsin

**ANSWER**—Unfortunately, trauma to any areas covering old osteomyelitis scars is apt to produce trouble, and the patient should always be warned to avoid injury to such areas. It is particularly prone to occur in the tibia when the fatty subcutaneous tissue has disappeared and the skin is adherent to the bone. When trauma is inflicted on such an area the skin does not have the normal mobility and the full force of the blow is expended on the devitalized tissue, and even though no true infection arises the skin may be so devitalized that it sloughs.

#### CLIMATE FOR ASTHMA

*To the Editor*—1 Could you suggest a locality in the United States which is best suited for an asthmatic patient? 2 Could you suggest a hospital or clinic in the vicinity of New England which specializes in the treatment of asthma?

M D Rhode Island

**ANSWER**—1 The only type of asthma which is affected to any appreciable extent by climatic conditions is that which is due to respiratory infection (paranasal sinuses or bronchi, especially bronchiectasis). Asthma due to these conditions is better in a dry warm climate (New Mexico, parts of Texas, Arizona and similar regions). It is unwise to send a patient with asthma to any of these regions without a thorough study of the effect of pollens, perennial inhalants, contact substances and foods.

many cases no matter where the patient goes he may be his enemy with him

There are numerous well trained men who specialize in various conditions all through New England, especially in the big centers, such as Boston, New York, Pittsburgh and Philadelphia. The larger hospitals in these cities have one or more men eminent in this field on their staff

#### HEPTYL ALDEHYDE AND MOUSE TUMORS

*To the Editor*—In the August 8 issue of *Time* page 24 under Cancer was an article on the active principle of wintergreen oil heptyl aldehyde being used experimentally by Dr. Strong of Yale Medical School in cancer in mice and dogs. How much truth is there in it and where heptyl aldehyde is obtained?

A GAEBLER M D Chicago

**ANSWER**—There is no reason to doubt the statement of Dr. Strong of Yale University Medical School that a certain number mouse and dog tumors have disappeared under treatment with heptyl aldehyde. There is no evidence at present that this treatment will be effective on human beings with cancer. According to Bernthsen (Organic Chemistry), normal heptylic aldehyde (heptanol)  $C_7H_{16}O$ , is obtained by the dry distillation of castor oil under diminished pressure. Eastman Organic Chemicals sells heptanol (Heptylic aldehyde) under Heptaldehyde B. P.  $42^{\circ}/10$  mm. Heptyl aldehyde can be made by any good organic chemist perhaps one of the large drug houses might prepare some.

#### EPIDERMOPHYTOSIS AND FUNGI ON DRESSED LEATHER

*To the Editor*—Many employees of a local shoe plant have epidermophytosis of the hands. The leather used often has a so-called fungous bloom on it. I understand this is a true fungous growth involving the leather. What type of fungus is this? Could it infect human skin?

M D Indiana

**ANSWER**—The only way to answer this question is by study of the fungus by a mycologist. It is probable that several kinds will be found on different lots of leather. Although undressed hides may carry ringworm infection to those who handle them (White, R. Prosser, *The Dermatogoses*, London, H. K. Lewis & Co., 1934, p. 375) the fungi growing on dressed leather are more probably "tramps," those whose spores are carried by the wind. These are ordinarily nonpathogenic to man but under certain circumstances may cause disease, as in infections of the external auditory meatus.

#### PEROXIDES OF BODY

*To the Editor*—Kindly advise me the specific names of five or six peroxides that are part and parcel of the human body and kindly state which of them are intracellular. It is said that hydrogen peroxide probably does not exist as such in the human body. Simons chemistry says acetic acid is found in the secretions of some glands but does not mention the glands. Sollmann speaks of acetyl peroxides as existing in the body but does not say where or how it is formed and Stirling speaks of the body having mixtures containing peroxides but no book of reference in my library specifically names any intracellular or extracellular peroxides of the body. The only organic peroxides that I find specifically named are those derived from other than animal life, such as benzoyl acetyl peroxide (benzozone acetozone), a benzoacetic ester and succinic peroxide (alpozone) both of which are obtained from distillation of fossils of plant life (wood coal).

G W TAYLOR M D Perth Amboy N J

**ANSWER**—A careful search of the literature up to the year 1937 failed to disclose any trace of peroxides that are part and parcel of the human body being isolated as such. The Manuel de biochimie of Pierre Thomas (Paris, Masson & Cie) writes in confirmation with the preceding statement "The presence of organic peroxides cannot be made evident."

#### AIRPLANE TRIP FOR BABY

*To the Editor*—A young mother with a 6 weeks old baby wishes to take a trip of about 800 miles. Is there any reason why it would not be advisable for her to go on an airplane? The baby is a normal healthy child. The trip would require about four or five hours of flying time.

M D Kansas

**ANSWER**—There should be no contraindication against a 6 weeks old baby taking a four or five hour trip by airplane presuming that the plane flies at a reasonable altitude. The ordinary changes in oxygen pressure, temperature, motion of the ship and other conditions met in airplane transportation should not affect a healthy, normal baby.

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in *THE JOURNAL*, January 21 page 265.

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS Parts I and II Medical centers having five or more candidates desiring to take the examination Feb. 13-15 May 12 (Part II only—limited to a few centers) June 19-21 and Sept. 11-13 Ex Sec Mr. Everett S. Elwood 225 S. 15th Street Philadelphia

#### SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY An Affiliate of the American Board of Surgery. Written examination Part I will be held in various cities of the United States and Canada April 8. Oral examinations for all candidates St. Louis May 13-14. Applications must be filed not later than sixty days prior to the date of the examinations. Sec. Dr. Paul M. Wood 745 Fifth Ave. New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY St. Louis May if there are sufficient applications before Feb. 1 to warrant holding an examination Philadelphia Oct. 30-Nov. 1 Sec. Dr. C. Guy Lane 416 Marlboro St. Boston.

AMERICAN BOARD OF INTERNAL MEDICINE Written examinations will be held in various parts of the United States Feb. 20 Sec. Dr. William S. Middleton 1301 University Ave. Madison Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY General oral clinical and pathological examinations for all candidates Part II examinations (Groups A and B) will be held in St. Louis May 15-16. Application for admission to Group A examinations must be on file in the Secretary's office by March 15. Sec. Dr. Paul Titus 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY Written Various cities throughout the country March 15 and Aug. 5 Oral St. Louis May 15 and Chicago Oct. 7 Sec. Dr. John Green 6830 Waterman Ave. St. Louis.

AMERICAN BOARD OF OTOLARYNGOLOGY St. Louis May 12-13 and Chicago Oct. 6-7 Sec. Dr. W. P. Wherry 1500 Medical Arts Bldg. Omaha.

AMERICAN BOARD OF PATHOLOGY Richmond Va., April 8-9 Sec. Dr. F. W. Hartman Henry Ford Hospital Detroit.

AMERICAN BOARD OF PEDIATRICS Cincinnati Nov. 15. Appointments must be made before July 15. Sec. Dr. C. A. Aldrich 723 Elm St. Winnetka Ill.

AMERICAN BOARD OF RADIOLOGY St. Louis May 11-14 Sec. Dr. Byrl R. Kirklin 102-110 Second Ave. S.W. Rochester Minn.

### Illinois October Examinations

Mr. Homer J. Byrd, superintendent of registration, Illinois Department of Registration and Education reports the written examination (graduates of foreign schools given also a practical test) held in Chicago Oct. 18-20, 1938. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Ninety-two candidates were examined, ninety of whom passed and two failed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Howard University College of Medicine	(1937)	79

## Book Notices

**The Foot** By Norman C. Lake M.D. M.S. D.Sc. Senior Surgeon and Lecturer on Surgery, Charing Cross Hospital, London. Second edition. Cloth. Price \$4.50. Pp. 366 with 113 illustrations. Baltimore: William Wood & Company, 1938.

This book is a real contribution and an invitation to members of the medical profession to increase their interest in the common ailments of the feet. In his preface the author refers to the comment of a reviewer of the first edition: "Provided that the reader realizes that this book was not written for any one in particular (i.e., surgeons, general practitioners, students, chiropodists, etc.), he will not be disappointed." Nevertheless it seems that the author, as a surgeon, has collected and published his studies and experience primarily for the general practitioner in order to help him within his own circle of patients to handle these cases understandingly and with confidence. The author's deep interest in the foot is indicated clearly by his method of presentation. By starting with a concise discussion of the evolutionary and embryologic phases of the foot's development, it is obviously his desire to build his reader's interest on fundamental knowledge of the foot and through a process of reasoning. Also he gives a brief history of the development of shoes, which is quite relevant since they have long been regarded as a common source of foot trouble. Criticisms have suggested that his inclusion of surgical measures and of unusual diseases and anomalies confuses the purpose of the book, especially since the discussion on these points is not always carried into full detail. Such criticism seems, however, to reveal the author's real purpose of the book as one for physicians. Admittedly it would be a useful member in the library of any orthopedic surgeon. As for the general practitioner, in addition to being familiar with what logically lies within his own range of helpfulness, it is necessary that he should also have some acquaintance with the less usual and more advanced conditions and their treatment. Otherwise he could not make recommendations to his patients as intelligently whenever more specialized surgical

or orthopedic services were required. Although the book covers the disorders of the skin, nails, toes and foot generally, the presentation of the functional disorders, affecting the longitudinal arch and metatarsal region, deserves special mention. Here, instead of a didactic repetition of orthodox views, the subject is discussed in the light of newer studies from different points of view. It challenges the exercise of the reader's own reasoning powers. This is a thoughtfully prepared book by an experienced clinician and able writer.

**Konstitution und Wesensänderung der Epileptiker** Von Dr. Karl H. Stauder, Facharzt für Nervenkrankheiten, München. Boards. Pp. 194 with 31 illustrations. Leipzig: Georg Thieme, 1937.

This monograph describes studies of the constitution and character of the epileptic. It is by a specialist (facharzt) in nervous disease in the mental and nervous clinic of Prof. Bumke. There are fourteen chapters divided into experimental and clinical material. The former consists of eight chapters in which Rorschach's studies in relation to all types of epilepsy are made. The clinical portion consists of six chapters and discusses character, mental symptoms and dementia in relation to all types of epilepsy. No new contributions are made. The bibliography is by no means complete. No mention is made of good work done by Americans in this particular field. The book is much too long. It serves no more than an additional work of reference regarding all the previously published facts on epilepsy and its mental and constitutional characters.

**Endocrine Therapy in General Practice** By Elmer L. Serrin M.D. F.A.C.P. Professor of Medicine, University of Wisconsin. Cloth. Price \$2.75. Pp. 192 with 39 illustrations. Chicago: Medical Book Publishers, Inc., 1938.

The recent rapid advances in the physiology and biochemistry of the endocrine glands have made it extremely difficult for the general practitioner to keep abreast of the diagnostic methods and of the potent therapeutic products of glandular origin which are available to him. This is rendered even more difficult by the necessity for distinguishing between the theoretical and the practical, the proved and the untried, the true and the false, in the confusing welter of periodical literature and commercial exploitation which assails the conscientious student of medicine. This book is intended to summarize the facts which may be accepted as proved in the present state of our knowledge and to apply these facts to the diagnosis and treatment of endocrine disorders, as far as they can be applied by physicians in general practice. The author is to be congratulated on the degree to which he has fulfilled his purpose. This volume is simply written, systematically arranged and well illustrated with excellent photographic plates of typical cases of endocrine dysfunction. Beginning with two short chapters on the biologic significance of hormones and an outline of systematic endocrinology, the author then treats each gland in turn. Syndromes are described, diagnostic procedures outlined, potent endocrine preparations listed and dosage given. An index is appended for rapid reference. This is not a book for the scientific investigator or the specialist in endocrinology; nor can it be expected to remain up to date for long. But it is a book which every general practitioner might read with pleasure and profit at this time.

**Posibilidades radiográficas en el cáncer de la faringe** Por Pedro Rebolledo, profesor agregado de otorinolaringología y Nicolás L. Caubarrere jefe de servicio de radiología del Ministerio de salud pública. Trabajo presentado en el VII reunión anual de la Sociedad rioplatense de otorinolaringología (29 y 30 de Enero de 1938). Paper. Pp. 72 with 76 illustrations. Montevideo: The Authors, 1938.

The authors review the radiographic examination in tumor of the larynx as suggested and studied by Coutard since 1922, adding to this the advantage of the recent study of the larynx by planigraphy or tomography. They arrive at the conclusion that the lateral view is indicated in cancer of the superior portion of the larynx as well as in the anterior subglottic tumors. They advise planigraphy in tumors of the medial portion of the larynx and in lateral subglottic tumors. The paper is illustrated with a large number of roentgenogram and drawings of the clinical conditions.

**Modern Surgical Technic** By Max Throck M.D. K.L.H. K.C. Prof. Clinical Surgery Cook County Graduate School of Medicine Chicago. With a foreword by Donald C. Balfour M.B. M.D. LL.D. Head of Section in Division of Surgery The Mayo Clinic Rochester Minnesota. Complete in three volumes. Volume I General Operative Considerations Surgery of the Head and Neck and Plastic Surgery. Volume II Surgery of the Thorax Vessels Bones Surgery of Breast and Chest. Volume III Abdominal Surgery Hernia Genito-Urinary and Gynecologic Surgery. Cloth Price \$33 per set Pp 526 527 1229 1231 2045 with 2174 illustrations. Originals principally by W. C. Shepard Philadelphia New York Montreal & London J. B. Lippincott Company 1938.

If it is possible to write a "stream-lined" modern version of surgical procedure and art, this three volume edition comes close to the mark. Surgery has reached a state of minute subdivision and there are now specialists in the surgery of individual organs. A vast literature has grown up in each of the various fields. The author has tried to dispense as much as possible with needless discussion. The work is divided in the usual manner into topographic divisions including the head and neck, chest, breast, hernia, abdominal surgery, pelvic and genito-urinary. Other portions include bones and joints, the neglected field of amputations, and other accessory information necessary to the surgeon.

This work reflects the author's experience. Much space is devoted to his method of electrocoagulation of the gallbladder. However, he follows this with an excellent description of Maingot's technic. He departs from usual conservative procedure in advocating a minimum of drainage following cholecystectomy, and he certainly understresses the necessity of examining the biliary tract at operation on the biliary system. Since this is a book which will appeal a great deal to the general practitioner who must also concern himself with surgery, his remarks on appendectomy and especially with regard to the McBurney incision and treatment of appendical stumps are highly pertinent. In the main, the usual accepted procedures are well described and the author gives full credit to the historical originators of an operation and his own and others' variations. The listed comments of various surgical authorities on the advantages or disadvantages of the methods described are a fascinating feature and acquaint the reader with a number of surgical personalities.

A working description of the anatomy accompanies each section in order to reacquaint the surgeon with the area. A fine feature is the diagrammatic description of the local anesthesia useful in that particular locale and for the various procedures to be attempted. This is in addition to the chapter on general and regional anesthesia at the beginning of volume I. The indexing is excellent and the author has solved one annoying problem by listing his references as footnotes to the pages on which they appear.

Numerous illustrations of high quality are spread with a lavish hand throughout. Dr. Thorek's well known artistic abilities have endowed him with that peculiar talent of selection in which every illustration serves its purpose and wherever possible speaks a volume of words. To busy practitioners and general surgeons these volumes should be of great service.

**Zur Erblichkeitsfrage des endemischen Kretinismus. Untersuchungen an 204 Kretinen und deren Blutsverwandten. Teil 1.** Von J. Eugster. Separatabdruck aus Archiv der Julius Klaus Stiftung für Vererbungs-forschung Sozialanthropologie und Rassenhygiene Band XIII Heft 3 1938. Paper Pp 383 494 with 110 illustrations. Zurich Art Institut Orell Füssli 1938.

Investigating the incidence of cretinism in regions previously studied for goiter incidence (*Arch. f. Hyg.* 81, 1913, and 111, 1933) the author found a marked similarity in geographic distribution. In localities in the cantons of Aargau and Zurich with a high goiter incidence, there were seventeen cretins among 1,627 inhabitants. In the middle range of goiter incidence there were only two cretins among 688 inhabitants, and in the endemic free localities not a single case of cretinism was found among 580 investigated in 1912 and again in 1932. The incidence of cretinic manifestations, in their various degrees of severity, was higher than previously assumed. In certain localities thirty-five cretins per thousand inhabitants were found and the average incidence was 6 per thousand for the total region previously investigated for goiter. Particularly interesting were the families studied in which cretinic characteristics marked an entire group of sisters and brothers.

A greater frequency among near relatives of the parents of cretins was not demonstrated in the material studied. The frequency in near relatives was not greater than the average for the total population. Among the children of healthy parents, the percentage of children affected was just as great as when one of the parents was cretinoid. In all cases in which the father was cretinoid and the mother was healthy there was no case of cretinoid children. In five families observed in which both parents were cretinoid the relatively high number of healthy children was notable. The investigation of brother and sister groups revealed a greater occurrence in the late births. Among people coming into the districts studied, cretinism may appear in the second, occasionally in the first, generation of children, but never was a case of acquired cretinism observed in the immigrants themselves. The investigation of twins indicated a nonhereditary anlage. There were nine identical and fifteen dissimilar pairs in the twenty-four pairs of twins. The concordance-discordance relationship of the first may be expressed 6:3 and of the latter 10:5. Definitely the dissociation of symptoms was revealed, that is, the manifestations of disturbance of growth does not parallel the other main symptoms such as defective hearing and lowered intelligence.

**Physical Diagnosis** By Richard C. Cabot M.D. and F. Dennette Adams M.D. Instructor in Medicine in the Harvard Medical School. Courses for Graduates. Boston. Twelfth edition. Cloth Price \$5. Pp 846 with 391 illustrations. Baltimore: William Wood & Company 1938.

This is an expanded revision of the previous editions embodying much that is new. The views of the co-author as well as those of the teaching staff of the Massachusetts General Hospital have been incorporated to give a much more complete volume on physical diagnosis. The arrangement with the increased emphasis on the relationship to symptomatology and clinical entities adds to the readability and the appeal to the medical student. The many new illustrations are well chosen and aptly supplement the text.

**The Handicap of Deafness** By Irene R. Ewing M.Sc. and Alex W. G. Ewing M.A. Ph.D. Cloth Price \$5.40. Pp 327 with 85 illustrations. New York Toronto & London Longmans Green & Co 1938.

This book accomplished a useful purpose. It tells in clear, succinct language of the handicaps and social disabilities of deafness and tersely may be summarized as presenting ways to alleviate incurable deafness. The deaf and the deafened, divided into class groups, are each accorded separate treatment in the text. The young of either sex who are becoming deaf, the middle aged with partial deafness, the child with defective hearing, and those born deaf each presents a different problem. The authors first present the problems with which each group is confronted and then they fully discuss in detail the steps to be undertaken to promote alleviation of the situation for each group. The book contains a great amount of first-hand study by the authors together with correlated scientific data not generally found collected in one volume. The book therefore is particularly valuable to educators and to students of the problems inherent in the education and the social and personal adjustment of the deafened in their everyday environment. The contents will also interest the medical profession. Otolologists will be amply repaid for reading about the influence of deafness on speech in the young and its effect on the adult who becomes deaf, chapters on the assessment of deafness, the distortions and loudness factors inherent in defective hearing, and the methods which the authors recommend to test intelligibility of speech. This is comprehensible when one realizes that the elements which go into the pathogenic lesions which result in deafness and those which promote the physiologic act concerned in listening are not too clearly comprehended by otologists. It would take us too far afield to open a discussion of the many interesting and provocative chapters which the authors of this book present. Perforce this must be omitted here, but the book is recommended for study by all interested in deafened persons. The stress on the educational phases to alleviate deafness is clearly emphasized and deserves special mention. The reader of this volume will be made to realize what a many-sided problem the persons handicapped by deafness present, and a path is outlined to alleviate the conditions which are the barriers to social, economic, medical and personal adjustment to an

otherwise incurable situation. Physicians generally, otologists particularly, and the social workers among the deafened will find in the book a valuable guide and source material. The book is written in such a way that it is commended to the League for the Hard of Hearing in this country for reading. It will help deafened persons to understand themselves and perhaps to help themselves.

*Revisão da família Trichostrongylidae Lelper 1912* Por Lauro Trassos. Monographias do Instituto Oswaldo Cruz No 1. Paper. Pp 512 with 295 illustrations. Rio de Janeiro. Typ do Instituto Oswaldo Cruz 1937.

This is a systematic monograph of an important family of nematode worms parasitic in vertebrates. It includes thirteen subfamilies, ninety-three genera and 335 species. They are known from all classes of vertebrates but only in one fish, a few amphibians, fewer reptiles and more birds and they seem to have reached their greatest evolution in mammals, in which they range from monotremes to man. Two species, *Haemonchus contortus* and *Mecistocirrus digitatus*, occur in man, the former being found also in the bear, pig, several ground squirrels, camel, reindeer, elk, caribou, several American deer, buffalo, many antelopes, sheep, goats, bison and cattle. The latter species has fewer hosts, being known only from the pig, cattle and Indian buffalo. The organs usually infested are the stomach and intestine. This monograph gives the bibliography, synonymy, measurements, morphology, organs infested, geographic distribution, and a diagnostic figure of each species but unfortunately no figures of ova. It will be of value to veterinary science and will help in the identification of the trichostrongylid worms which man may occasionally pick up from his domesticated animals. It is interesting to note that man has not inherited any of eight species of these worms found in other primates.

*La anemia de la enfermedad de Carrion (verruca peruana)*. Por el Dr. Alberto Hurtado, profesor de fisiopatología y director del Laboratorio de Investigaciones y Srs. Julio Pons M. y Cesar Merino M. ayudantes del Laboratorio de Investigaciones. Laboratorio de Investigaciones. Departamento de fisiopatología. Facultad de ciencias medicas. Lima. Paper. Pp 206 with 53 illustrations. Lima. Peru. Libreria e Imprenta Gil S. A. 1938.

This is a report of investigations on the morphology of the blood and other characteristics of the anemia resulting from Carrion's disease (verruca peruana). Forty-six cases of this disease were studied and the results compared with similar observations on a hundred normal subjects. The authors conclude that the anemia which is frequent and severe in this disease is characterized by (1) its great rapidity of development, (2) macrocytosis, (3) anisocytosis and (4) hypochromemia. The degree of the last three of these characteristics was directly proportional to the severity of the anemia. The erythrocytes increased in thickness more than in diameter, tending to become spherical. Determinations made on total blood volume revealed an intense reduction in total circulating erythrocytes and hemoglobin with a compensatory increase in quantity of plasma, an increase which exceeded the erythrocyte loss in certain periods of the anemia, thereby effecting a cellular dilution. This would introduce a moderate error in the estimation of the anemia when the latter is determined solely by the numbers of cells per unit volume of blood. Hyperbilirubinemia was observed in the majority of cases. It was greatest during the periods of greatest anemia and, in fatal cases, during the last few days of life. There were indications that the jaundice was related to the greater erythrocytic destruction and to a diminution in the excretory power of the hepatic cells. Frequently an increased fragility of the red cells accompanied the period of intense anemia. Parasitism of the erythrocytes by *Bartonella bacilliformis* was rather constant during the anemia. The majority of cases showed signs of intense erythropoietic activity which was proportional to the degree of the anemia. This was responsible for the macrocytosis, hypochromemia, reticulosis and the presence of normoblasts in the blood.

The leukocytes occurred in normal numbers in uncomplicated cases, with an occasional leukopenia. During the period of greater anemia a moderate "regenerative reaction" and a more intense "degenerative reaction" occurred. When "cellular crises" occurred they came at times when the leukocytes were

between 24 and 32 millions per cubic millimeter and were apparently not related to the erythrocytic regeneration. This crisis corresponded, in general, to the time at which the parasitism and the signs of abnormal cellular destruction disappeared.

Achlorhydria and hypochlorhydria were evident in the majority of cases. Liver therapy did not arrest the anemia but apparently did accentuate the processes of regeneration.

The appearance of macroscopic eruptive lesions did not correspond to a definite level of cells per cubic millimeter but in three cases was preceded by the "cellular crisis." The morphologic similarities between Carrion's anemia and the experimental bartonellosis in animals (*B. canis* and *B. muris*) are discussed. The authors believe that the pathologic mechanism in Carrion's anemia consists fundamentally of an accentuation of the processes of cellular destruction.

They conclude that their results suggest the need for including liver extracts and iron in the treatment.

*Arbeit und Gesundheit. Sozialmedizinische Schriftenreihe aus dem Gebiete des Reichsarbeitsministeriums. Herausgegeben von Professor Dr. Martineck, Ministerialdirektent im Reichsarbeitsministerium. Heft 3: Tabes dorsalis. Klinische, erb- und konstitutionspathologische sowie sozialmedizinische Untersuchungen. Unter Verwertung der Erfahrungen aus der Kriegsbeschädigtenversorgung. Von Prof. Dr. F. Curtius, Dr. med. H. Schlotter und Dr. phil. Edm. Scholz. Paper. Price 14 marks. Pp 275 with 80 illustrations. Leipzig: Georg Thieme 1938.*

This study of 101 tabetic patients is of little value to the clinician. Of the 262 pages of text, 160 are devoted to a survey of constitutional, individual and familial predisposing factors and thirty-eight to the effect of war service on the development of tabes. Only thirty-nine pages are given to clinical considerations and no space is allotted to treatment. On the whole, the monograph might more profitably have been presented as a series of short papers in the periodical literature. The conclusions, based on an elaborate presentation of individual case histories, tables and charts, are that the various factors of human constitution studied by the authors are not concerned in the pathogenesis of tabes, except bodily habitus, which is frequently of the asthenic type (though it is not made clear whether patients develop tabes because they are asthenic or become asthenic after they develop tabes) and "neuropathic constitution." By the latter is meant that the families of tabetic patients include a higher proportion of psychiatrically unstable persons than do those of normal people. Many constitutional factors are considered in great detail and, though the results are largely negative, the work will be of value to students of this phase of medicine. With characteristic German disregard of science elsewhere than in Germany, the bibliography of 160 references includes 147 to German authors, eleven to French, one to an Italian and one to an English speaking author, the last to a twenty-four year old article by C. J. White (*A Statistical Study of Syphilis. The Relation of Its Symptoms to Subsequent Tabes Dorsalis and General Paralysis*, *THE JOURNAL*, Aug. 8, 1914, p. 459) and even this lone English article is incorrectly cited.

*The Sex Criminal*. By Bertram Pollens. Foreword by Richard L. McGee, Warden, Rikers Island Penitentiary. New York City. Cloth. Price \$2. Pp 211 with 5 illustrations. New York: Macaulay Company 1938.

In his preface the author makes acknowledgment to great numbers of officials in New York who have aided him with advice and opportunities in the development of this book. The author is senior psychologist to the penitentiary of the city of New York and as such has had administrative charge of the sex clinic in association with psychiatrists and technicians. The book takes up the matter from the point of view, therefore, of the physician and of the psychologist, as well as from that of the lawyer. Each year about 1,500 so-called sex criminals are arrested in New York City. Sex crimes, however, are more frequent, the number apparently decreasing from about 7,000 in 1923 to 3,700 in 1935. The author approaches the subject from the Freudian point of view, one of his most extensive chapters being that entitled "Infantile Sexuality." It seems doubtful, however, that many Freudians would recognize this author as competent for such a performance. Later chapters are concerned with homosexuality and sexual deviations. Fortunately the conclusions of the author are much more sound

than the discussions which gave them birth. He recommends psychiatric studies of the sex criminal and of the subject of sex in childhood, sympathy by parents with the problems of the child and sex education in the home.

**A Historical Chronology of Tuberculosis.** By Richard M. Burke, M.D. State Veterans Hospital Sulphur, Oklahoma. Cloth Price \$1.50. Pp. 84. Springfield, Illinois & Baltimore: Charles C. Thomas, 1938.

Our knowledge of tuberculosis is as old as our knowledge of medicine itself. Evidence of tuberculosis of the spine have been found in men of 5000 B.C. The poet Homer refers to the disease and Hippocrates provided the first detailed description of the nature of tuberculosis. Year by year since that time medicine has added important foundation stones to our knowledge. The following significant dates in the history of tuberculosis have proved most important:

460-370 B.C. Hippocrates provides an accurate clinical description of phthisis.

1679 Sylvius sees tubercles (nodules in the lung) as the actual precursors of phthisis.

1810 Bayle teaches that tubercles are a specific local formation causing a specific disease.

1815 Laënnec establishes the unity of the tubercle. He discovers the stethoscope and founds modern physical diagnosis.

1859 Brehmer begins the modern institutional treatment of tuberculosis.

1865 Villemin demonstrates experimentally that tuberculosis is a specific infection due to an inoculable agent.

1882 Koch discovers the cause of tuberculosis, the tubercle bacillus.

1890 Koch introduces tuberculin, a glycerin extract of tubercle bacilli.

1894 Forlanini pioneers the use of artificial pneumothorax in the treatment of pulmonary tuberculosis.

1895 Roentgen discovers x-rays.

1907 Pirquet introduces a cutaneous test for tuberculosis.

**Einführung in die chemische Physiologie.** Von Dr. E. Lehnartz, a.o. Professor an der Universität Göttingen. Second edition. Paper. Price 18 marks. Pp. 434 with 70 illustrations. Berlin: Julius Springer, 1938.

This book presents a more thorough treatment of the organic chemistry of carbohydrates, lipids and proteins than appears in any of the recent textbooks of biochemistry in English. It may be useful to some readers for that reason. Approximately 100 pages are devoted to what might be considered pure organic chemistry. The next fifty pages are devoted to physical-chemical questions, the treatment of which introduces more biologic material, however, it would still seem possible to devote more attention to specific physiologic questions. Vitamins, hormones and enzymes occupy the next section, of 120 pages. The treatment of these questions is thoroughly down to date and includes an adequate amount of physiologic material. The rest of the book, 140 pages, is devoted to metabolism. This section of the book is closely packed with important information but is somewhat too short to accomplish a satisfactory treatment of the subjects in question. The whole problem of fat metabolism, for example, occupies only six pages. The treatment of what might be called clinical chemistry is almost completely lacking.

**Acidosis y alcalosis en la clínica.** Por B. Varela Fuentes, profesor de la Facultad de medicina de Montevideo. Prólogo del Profesor Gregorio Marañón. Paper. Pp. 445. Buenos Aires: Espasa Calpe, Argentina. S. A. 1937.

In this book the author studies the acid-base equilibrium, both normal and pathologic. The book is divided into three parts, which deal respectively with the normal acid-base equilibrium from biochemical and physiologic angles, the various types of acidosis and alkalosis and their pathogenesis, and the treatment of the various types of acidosis and alkalosis which are observed by practitioners of internal medicine, clinical surgery, pediatrics, urology, gynecology and several other medical specialties. Special reference is made to the treatment of grave conditions caused by the rupture of the acid-base equilibrium which have to be rapidly controlled by introduction, in the blood, of a radical amount of which is insufficient in the blood plasma, such as, for instance, rechloridation in alkalosis from hypochloremia and administration of injections of sodium chloride solutions in the course of Addison's disease and of calcium in hypocalcemia in

tetany. The subject, on the whole, is dealt with in a precise, clear, didactic and interesting style, covering the various fields of theory and clinical practice. The literature is critically reviewed and there is a selected bibliography. The book contains graphic illustrations and tables of the most important points related to the acid-base equilibrium, both normal and pathologic. It ends with a subject index. The book is of value for physicians in the various medical specialties, especially Spanish-speaking physicians.

**A Manual of Surgery for Nurses.** By Charles Wells, M.B., F.R.C.S., Honorary Surgeon with Charge of Out Patients, Royal Southern Unit of the Royal Liverpool United Hospital, Liverpool. Cloth. Price \$4. Pp. 409 with 160 illustrations. Baltimore: William Wood & Company, 1938.

This is a small, non-exhaustive book on surgery, intended primarily to introduce the student nurse to the science and art of surgery as well as to prepare her for the required state examinations. The book, though brief, is unusually complete. It covers all of general surgery including gynecology, orthopedics and the conditions of the eye, ear, nose and throat. It does not, however, deal with any of the practical nursing procedures. Written in simple clear style and illustrated by line drawings to clarify the text, it easily fulfils the purpose for which it was intended.

**Symptoms of Visceral Disease. A Study of the Vegetative Nervous System in Its Relationship to Clinical Medicine.** By Francis Marion Pottenger, A.M., M.D., LL.D., Medical Director, Pottenger Sanatorium and Clinic for Diseases of the Chest, Monrovia, California. Fifth edition. Cloth. Price \$5. Pp. 442 with 97 illustrations. St. Louis: C.V. Mosby Company, 1938.

The latest edition of this well known book is not greatly altered from the earlier printings. Attention is called to the close interrelations between the vegetative nervous system, the glands of internal secretion and the electrolyte balance. One may not agree either with the argument or with the conclusions, but one must admit that the book is always interesting and stimulating.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Charitable Hospitals Liability to Pay Patient for Negligence of Employee.**—An appendectomy was performed at the defendant hospital on the plaintiff's minor son, a pay patient. Subsequent to the operation, a nurse employee of the hospital injected one-fourth grain of morphine, instead of the one-fourth grain of codeine ordered by the attending physician. The patient died soon thereafter from the effects of the injection. The plaintiff then sued the hospital. The defendant hospital demurred to the complaint, contending that it was incumbent on the plaintiff to plead that the hospital was *not* a charitable institution, which he had not done. The plaintiff appealed from the judgment of the trial court sustaining the demurrer, and the Supreme Court of Utah reversed the judgment and remanded the cause to the trial court with directions to overrule the demurrer. *Sessions v. Thomas Dee Memorial Hospital Ass'n*, 89 Utah 222, 51 P. (2d) 229 (abstr. J. A. M. A. 107 453 [Aug. 8] 1936). After the demurrer was overruled by the trial court, the plaintiff amended his complaint so as to allege in effect that, even though the defendant hospital was a charitable institution so far as its organization, aims and purposes were concerned, nevertheless it was liable for the negligence of its employee because the person injured as a result of the negligence was a pay patient. The defendant hospital then demurred to the amended complaint and when the trial court sustained that demurrer and entered judgment for the defendant the plaintiff again appealed to the Supreme Court of Utah.

The Supreme Court, citing with approval *Henderson v. Twin Falls County*, 56 Idaho 124, 50 P. (2d) 597 (abstr. J. A. M. A. 106 1228 [Apr. 4] 1936) held in effect that where a hospital has entered into a contract to render service to a patient for compensation, even though the general purposes of the hospital are charitable, it is liable to that patient for injury caused by

the negligence of its nurse employee. Accordingly, the judgment of the trial court was reversed and the cause again remanded with directions to overrule the demurrer.

In a dissenting opinion the chief justice and another justice were of the opinion that a charitable hospital is not liable for the negligence of its servants, whether the person injured be a charity patient or a pay patient, when it uses reasonable care in the selection and retention of its employees.—*Sessions v Thomas D Dec Memorial Hospital Ass'n (Utah)*, 78 P (2d) 645

**Compensation of Physicians Liability of County for Nonemergency Medical Services to Indigent**—On June 4, 1935, a woman resident of Noble County, Okla., was severely burned. On June 7, after self treatment proved unsuccessful, a physician, one of the six plaintiffs who as copartners operated a clinic, was called. As the patient was an "indigent person" within the meaning of the statutory definition of that term, the physician attempted to get into touch with a member of the board of county commissioners, who by statute were designated as overseers of the poor, to obtain authorization for her admission to a hospital at Perry as a county patient. He was unsuccessful. Failing to obtain such authorization, he nevertheless sent the patient to that hospital for admission as a county patient, but admission was refused. At the direction of the plaintiffs, she then was taken for treatment to the plaintiffs' own hospital at Ponca City. Two days before she left their hospital, the plaintiffs filed a claim with the county clerk for their fee for services rendered. The board of county commissioners, however, refused to pay, because they had not authorized treatment, and the plaintiffs brought suit against the board. From a judgment in favor of the plaintiffs, the board appealed to the Supreme Court of Oklahoma.

To support their claim, the plaintiffs cited *Board of Commissioners of Garfield County v End Springs Sanitarium & Hospital* 116 Okla 249, 244 P 426, in which the Supreme Court of Oklahoma said:

The general rule is that in cases of emergency attendance of a proper physician may hold the county liable although he acted without the request or the consent of the persons designated by statute as overseers of the poor where such poor person requires the immediate attention of a physician who renders services to relieve the necessity and where it appears that the board of county commissioners was not in session at the time and that notice could not have been given to the board of county commissioners before rendering necessary medical and surgical services the physician and surgeon may recover reasonable compensation from the county within the limit of the fund provided by law for such purpose.

But, said the Supreme Court, in the present case it has not been shown that an emergency existed which would not permit delay. The evidence showed that when the patient was admitted to plaintiffs' hospital her condition was critical but was not one of imminent danger to life. The evidence showed further that the plaintiffs did not have and did not attempt to obtain authorization for themselves to render medical and hospital services. The court concluded, therefore, that the county was not liable and so it reversed the judgment of the trial court and remanded the case with direction to enter a judgment accordingly.—*Board of Comrs of Noble County v Niemann et al (Okla)*, 78 P (2d) 672

**Optometry Practice Acts Corporation May Not Practice Optometry Through Licensed Optometrists**—The plaintiffs, individually as licensed optometrists, and as trustees of the Philadelphia County Optometric Society, and the Pennsylvania Optometric Association, instituted this suit to enjoin the defendant corporation from practicing optometry. The trial court entered a decree enjoining the defendant from holding itself out as an optometrist, by advertisement, sign or otherwise, and from practicing optometry. The plaintiffs, not being satisfied with the decree as entered, appealed to the Supreme Court of Pennsylvania, urging that the decree be enlarged specifically to prohibit the defendant from employing licensed optometrists to examine the eyes of its customers.

The defendant corporation leased a portion of its store to a partnership which operated therein an optical department for the examination of eyes and the fitting and supplying of glasses. This leased portion of the store was known and operated as the "Optical Goods Department." The lease was of indefinite duration but might be canceled on thirty days'

notice. The rental was \$12,500 a year, plus one third of the lessee's gross annual business in excess of \$50,000. The lease provided that the name of "Gimbels" should alone be used in advertising the department and obligated the lessees to expend a certain percentage of their annual sales, at least \$3,000, in advertising under the name and direction of the defendant. The store sign outside the leased department read "Gimbel Brothers' Optical Department." Prior to the commencement of the present suit, advertisements appeared under the name "Gimbel's Modern Optical Shop" with no mention of the names of the registered optometrists in attendance. Thereafter, the advertisements did name the optometrist actually in charge of the department. The registered optometrists in attendance and all other employees of the department were hired and paid by the partnership but were under the supervision and control of the corporation, which had a right to dismiss them. The registered optometrists did not conduct a practice of their own and were required to charge for all examinations and fittings of glasses in the defendant corporation's name and the corporation received all fees therefor. The charges for services rendered by the optometrists were fixed by the partnership but were required to be as low as in any other department store in the city, so as successfully to compete. Bills rendered for the examination of eyes and their fitting with glasses were in the defendant's name and on its billheads.

The plaintiffs conceded that the defendant corporation had a right to lease space in its store to a person to carry on his professional calling but contended that, when the leasing was accompanied with such control as was here shown, the lessee becomes the agent of the defendant, and since it cannot obtain a license to practice optometry it may not engage in such practice through agents. With this contention the Supreme Court agreed and in doing so quoted from the decision of the Supreme Judicial Court of Massachusetts in *McMurdo v Geller*, 10 N E (2d) 139, as follows:

The defendants contend that they are not practicing optometry illegally although they are not registered optometrists and yet reap all the financial reward of a practice conducted by their servant who is a physician and as such entitled to practice optometry without registration. A different rule has been applied to the learned professions. There are characterized by the need of unusual learning, the existence of confidential relations, the adherence to a standard of ethics higher than that of the market place and in a profession like that of medicine by intimate and delicate personal ministrations. Professional men may be held to a higher ethical code for example by the restriction of advertising than men engaged in ordinary business. The rule is generally recognized that a licensed practitioner of a profession may not lawfully practice his profession among the public as the servant of an unlicensed person or a corporation and that if he does so the unlicensed person or corporation employing him is guilty of practicing that profession without a license. A corporation as such cannot possess the personal qualities required of a practitioner of a profession. Its servants though professionally trained and duly licensed to practice owe their primary allegiance and obedience to their employer rather than to the clients or patients of their employer. The rule stated recognizes the necessity of immediate and unbroken relationship between a professional man and those who engage his services.

Expressing itself as fully in accord with the views thus voiced by the Massachusetts court, the Supreme Court of Pennsylvania in the present case concluded that the decree of the trial court should be enlarged to prohibit the defendant from employing registered optometrists to examine the eyes of its customers. It ordered the decree to be modified accordingly.—*Neill et al v Gimbel Bros, Inc (Pa)*, 199 A 178

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Giardiasis in Children**—Veghelyi states that of 1,391 children between the ages of 2 and 17 years examined for infestation with *Giardia lamblia* 155 proved to be positive. Of these only 144 could be precisely examined. In addition to tests for tuberculosis and syphilis, careful roentgen and electrocardiographic examinations and detailed laboratory tests were made in the majority of the cases in order to eliminate the possibility that causes other than *Giardia* were responsible for the condition. Thirty-two children gave evidence of various other diseases and twenty gave a positive reaction to tuberculin. Ninety-two children were left. All the symptoms found were compared with those of healthy children of the same age. Some infested children were symptomless and some had symptoms of no significance. But gastrointestinal complaints, anemia and inadequate development were present in a high percentage of cases. Aside from the common infectious diseases without complications, the histories showed that six children had dysentery and two typhoid from two to five years before the present examinations. Anorexia, headache, dizziness and abdominal pain were frequent. From one third to more than one half of the children had these

complaints. Pain in the abdomen together with loss of weight and anemia was often observed by the parents of the children. Intense, acute pain over the cecal region occurred independently of meals and appeared in cramplike attacks. Mucus, pus or blood had been seen in the feces of one fourth of the children who were infested. Two thirds complained of irregular bowel movements. Similar conditions cannot be found in healthy children. Fifty-one of the infested children were asthenic while only thirteen were of athletic constitution. No pathologic condition could be revealed by the physical examination of the lungs, hearts and kidneys of the ninety-two infested subjects. The most striking difference between the infested and healthy subjects was shown by the comparison of weights. Of the ninety-two infested children only thirteen attained or surpassed the average weight, while seventy-nine were below it. The development of their height was but slightly impeded. The hepatic disorders often found in adults were not present in these patients. All the symptoms may be explained by the impeded resorption capacity of the intestinal tract. The symptoms disappeared in twenty-nine of thirty-two children after treatment with acetarsone. Regeneration of the blood of anemic children and rapid development of those who were retarded in weight quickly started after successful treatment. Healing was not a consequence of the tonic action of arsenic. In the three cases in which treatment was not successful the symptoms were further aggravated.

**Sulfanilamide for Gonorrhea in Children**—Adler used sulfanilamide in the treatment of twenty-two cases of gonorrheal vaginitis, five of gonorrheal urethritis in boys and nine cases of gonorrheal conjunctivitis. The dose of sulfanilamide used was calculated on the recommendation of Long and Bliss, 1 Gm to 20 pounds (9 Kg) of body weight being given daily in three or four doses at equal intervals throughout the twenty-four hours. Eight of the nine patients with conjunctivitis responded promptly to sulfanilamide therapy, irrigations were required only at intervals of two or three hours after one or two doses of the drug and were discontinued after a few days of treatment. The results add further evidence to the report of Willis that, in cases of gonorrheal conjunctivitis, sulfanilamide gives a more rapid cure than any other method of treatment. In four of the five cases of urethritis there was a prompt response to treatment. Thirteen of the twenty-two children with vaginitis showed a prompt and definite response to sulfanilamide therapy, with cessation of discharge and with consistently negative smears after an average of two days of treatment. Three failed to respond to an adequate trial with sulfanilamide but the infection cleared up subsequently by treatment with estrogen, only to recur within a short time and respond satisfactorily within forty-eight hours to a second trial of sulfanilamide. An inadequate dose of the drug seems to account for three failures. In one other case in which there was no response the concentration of the drug in the blood, from 12.6 to 25 mg per hundred cubic centimeters, suggests that dosage and the concentration in the blood are not the only factors which determine success or failure.

**Active Immunization Against Whooping Cough**—In order to determine the prophylactic value of various whooping cough vaccines, Siegel followed up 1,270 vaccinated and 1,016 control children for from fourteen to twenty-three months. There were eight groups of vaccinated children under consideration. Familial exposure occurred in 1 per cent of all cases and extrafamilial exposure in 49 per cent. There were forty-six cases of characteristic whooping cough among the vaccinated children, as compared with forty-three among the controls. The incidence of characteristic whooping cough ranged from 0 to 6.72 per cent among the various groups of vaccinated children. It was lower among those inoculated with 80 billion bacilli than among those inoculated with smaller doses. There were no occurrences of characteristic whooping cough in two groups, 294 children, who were inoculated subcutaneously with 80 billion bacilli of Sauer's vaccine or the vaccine of the New York Department of Health. Familial exposure occurred in only one case, no symptoms developed in this instance. Extrafamilial exposure was suspected in ten cases, in three of which a cough unaccompanied by a whoop developed. Doses of 50 billion bacilli or less seemed to have little, if any, prophylactic value, this also seemed to be true of doses of 80 billion bacilli of a vaccine prepared from an old stock strain.

**Toxemia of Pregnancy and the Placenta**—According to Bartholomew and Colvin, placental infarcts of the more acute types are definitely associated with toxemia of pregnancy. The hypercholesteremia of pregnancy is the basis for vascular changes in the placental arteries which predispose to infarction. Hypothyroidism and a diet rich in cholesterol-containing foods are important factors in excessive hypercholesteremia. The trauma of fetal movements on the placental arteries in the latter part of pregnancy is not only a predisposing cause of localized cholesterol change in the vessels but also an exciting cause of thrombosis or rupture at the site of such change, with resulting infarction. The high content of arginine in placental tissue is the probable explanation of the specific eclamptogenic character of placental autolysate, through the formation of guanidine. The known pathologic effects of guanidine, peptone and histamine apparently explain the clinical and pathologic manifestations of toxemia of pregnancy. The results of a gross examination of 100 placentas from both toxic and normal cases, without knowledge of the clinical history, shows that it is possible to diagnose the occurrence of severe toxemia in 90 per cent of the cases. Conversely, it is possible to predict the type of infarcts that will be found in the placenta, from a knowledge of the clinical history of the pregnancy as to toxemia. With the experience of examining placentas as "unknowns," it has been found possible to establish criteria for an exact classification of placental infarcts and their relation to toxemia.

**Body Temperature and Fertility**—Zuck presents data which offer a practical method for the regulation of conception in fertile women. They may also be valuable in the study of women who are reputedly barren. In an effort to obtain further information on human ovulation, he began in 1930 to collect instances of carefully recorded coital exposure which resulted in pregnancy. He enlisted the assistance of young women planning pregnancy and willing to serve in an experiment in which the time of the midperiod could be determined. The women were instructed to keep menstrual records and to observe signs of the midperiod (mittelschmerz). From 1935, morning rectal temperatures also were taken by the women. Rupture of the follicle may actually be felt by the woman after careful observation of her own temperature curve. Sixteen planned pregnancies were successfully started by using midperiod symptoms as indicative of rupture of the ovarian follicle. There were no exposures during the cycle other than those indicated and no subsequent exposures until after pregnancy had been proved. No pregnancy occurred before the eleventh day of the cycle or after the eighteenth day regardless of the length of the cycle. Pregnancy never occurred at any other date of the menstrual cycle despite exposures permitted in previous months during the assumed sterile days. When the daily rectal temperature records are plotted, the resulting curve usually shows that just before menstruation begins there is a slight fall in the temperature, which in most women reaches 98 F. This level is main-

tained during menstruation. At the end of the period there may be a temporary lowering of the temperature, which then rises to somewhat above 98 F before falling abruptly, to reach its lowest level at the midperiod, when it may descend to 97 F or even lower. After this fall the temperature rises to a level usually above 98 F and remains about stationary until the onset of the next menstrual period. This phase is usually regarded as the lutein phase. Not all menstrual cycles show these clear cut variations, but in the sixty-seven women studied this variation was characteristic of more than 80 per cent of the menstrual cycles. Records of the last menstrual cycles of twenty women identify ovulation with the approximate date of the midperiod low temperature. No pregnancy occurred before the tenth day or after the twentieth day of the cycle regardless of the length of the cycle. In no woman did pregnancy occur more than three days before or one day beyond the initial rise of temperature from the midperiod low level. After conception the temperature no longer undergoes a cyclic change except in those few women who menstruate or perhaps even ovulate after pregnancy starts. The temperature during pregnancy remains high, as in the last part of the menstrual cycle, and can be used as a sign of pregnancy before other methods of diagnosis are positive. In every woman the morning nausea started at what by computation would be the date of the next ovulation after conception. Hence morning sickness of pregnancy may be related to a change in the ovulation cycle. The human fertile period is shown to vary from woman to woman and from cycle to cycle. It is necessary to study each woman's variation in order to understand her particular variability. As a minute method of determining the time of ovulation the basal rectal temperature is offered, since it is easily determined and bears a close relation ship to the time of ovulation. Studies of basal body temperature may be used as a guide or to supplement other data in studying sterility.

**Infections Causing Leukorrhea During Childbearing Period**—Poindexter states that of 1,975 patients examined during a venereal disease survey in Tallahatchie County, Miss., in 1937, 399 gave leukorrhea as a chief symptom, 318 of these women were in the childbearing age and eighty-one had passed the menopause. The infectious agents which should be considered in patients who present the symptom of leukorrhea as a primary complaint during the childbearing age are *Neisseria gonorrhoeae*, *Trichomonas vaginalis*, *Haemophilus ducreyi*, *Monilia albicans*, various streptococci and staphylococci, coryne bacteria and Vincent's spirillum. The frequency, about 50 per cent, with which nongonococcal organisms appear in cases of infectious leukorrhea warrants microscopic examination and culture if necessary for *Trichomonas vaginalis* and *Monilia albicans*. This is especially important when sulfamidamide is to be used. Sulfamidamide therapy is most effective when used in acute cases of gonorrhea and has no significant effect on leukorrhea due to *Trichomonas vaginalis*. There is an apparent antagonism between *Trichomonas vaginalis*, *Monilia albicans* and Doderlein bacilli against the gonococcus in vivo.

**Psychoses Among College Students**—Raphael and Gordon discuss the experience of the psychiatric unit of the student health service established in 1930 at the University of Michigan. The total enrolment during the seven years in question was

85,543, with a yearly average of 12,220. The number of students coming to the attention of the mental hygiene service was 4,779, an average of 7.67 per cent. In 114, psychoses of various types were observed. Of the 114 individuals developing psychoses sixty-four were men and fifty women. The average age range for schizophrenia was from 17 to 40, for the manic depressive group from 17 to 43 and for the paranoid conditions from 19 to 56 years. Psychoses among the student population, while not frequent, do represent a definite contingency which the college must appreciate and be prepared to meet. Properly approached and with adequate facilities, the problem can be satisfactorily dealt with, often with an excellent long-term result to the individual and academic result. In the college situation an almost unique opportunity is afforded for the early detection, study and treatment of psychotic conditions, actually in their incipience. In this naturally there should be much of benefit to the individual and, respecting the schizophrenic reaction type particularly, to the science of psychiatry itself through the realization of the mental hygiene principle. A psychiatric unit of the student health service of a college or university may further the institution's fundamental objective and the psychiatrist may render a vital and far reaching service.

**Barium Sulfate in Colloidal Aluminum Hydroxide**—Woldman recommends barium sulfate suspended in colloidal aluminum hydroxide for roentgenographic examination of the gastrointestinal tract as having advantages over the barium-water mixture now generally employed. Because of the colloidal nature of the aluminum hydroxide, the barium is held in suspension and hence can be used in smaller quantities. In these studies 60 Gm of barium sulfate was added to 7 ounces (210 cc) of a mixture of equal parts of colloidal aluminum hydroxide and water to form the contrast substance. The preparation is fluid so that it enters all the recesses in a homogeneous manner, and yet viscid and tenacious so that a small quantity coats the wall of the digestive tract and yields a satisfactory roentgenographic visualization of the mucosal folds. The barium sulfate-aluminum hydroxide suspension is nontoxic and does not alter the acid-base equilibrium of the blood. The addition of aluminum hydroxide to the barium mixture does not render it less palatable.

**Pyelo-Ureterography**—As an aid in the diagnosis of obscure lesions of the urinary tract, Price always takes a flat pyelo-ureterogram in the horizontal supine position. Then the usual cystoscopic examination is done, followed by sodium iodide or sodium ortho-iodohippurate injection, and another pyelo-ureterogram is taken in the Trendelenburg position. Following this the catheters are drawn down and a pyelo-ureterogram is

taken in the erect position. The films may be flat, stereoscopic, oblique or lateral. These positions afford maximal excursion of kidneys and ureters and afford valuable information in determining whether a given condition is postural, functional or organic. The lesions of the ureter, well shown by this routine, include calculus, stricture, kink, stenosis, adhesions, reduplication, mucous membrane valves, megalo ureter, aberrant implantation, atresia, fascial bands, anomalous vessels, extra-ureteral pressure, neoplasms, cysts, granuloma, chronic ureteritis, rupture into the duodenum and secondary calculus.

- \*Mapharsen in Treatment of Congenital Syphilis. V A Cornell and G D Astrachan New York—p 943

**Cosmetic Irritants**—Tulipan points out that cosmetic dermatitis usually appears abruptly and is characterized by erythema, edema, papules, vesicles, exudation, crusts and finally desquamation. It tends to form patches with indefinite borders and is usually accompanied with pruritus. When the condition is chronic the skin becomes thickened, infiltrated, pigmented and fissured. Clinically and microscopically the condition is indistinguishable from eczema. Perfumes, hair dyes, face powders and lotions and, in fact, practically all toilet articles containing such general irritants as alkalis, even though in small quantities, have at some time given rise to dermatitis venenata. Cosmetic preparations may cause irritation of the skin ranging from slight erythema to severe burns. Any product capable of producing such lesions among consumers is even more dangerous to workers in the cosmetic trade. The harmful ingredients in various cosmetics include lead, mercury, pyridine, denatured alcohol, isopropyl alcohol, arsenic, paraphenylenediamine, potassium carbonate, pyrogallol, alkaline sulfides, thallium acetate, salicylic acid, phenol, copper, ammonium and sodium carbonate, silver nitrate, aluminum salts, quinine, quinone bodies, acetone, colocynth, dimethyl sulfate, nitrobenzene, essential, natural and synthetic oils, alum and talc.

**Treatment of Dermatophytosis with Vaccines**—On the basis of reports that fungicidal elements existed in the serum of patients with dermatophytosis, Tolmach and Traub prepared a convalescent serum. Their results in sixty-five cases have been so unfavorable that they publish them in order to discourage the waste of patients' time and money and physicians' efforts and to point out that much more experimental work is necessary before such products will have any practical use. Three different vaccines were used. More than 60 per cent of patients were entirely unimproved by the treatment. About 9 per cent were apparently cured. The reports of cure and of improvement are subject to question.

**Mapharsen in Congenital Syphilis**—Cornell and Astrachan confirm the low toxicity of mapharsen stressed by almost all investigators. The serologic reactions in more than 50 per cent of their thirty-one cases of late congenital syphilis improved as a result of the treatment. This percentage is a fairly good one.

in cases of late congenital syphilis, in which biologic cure is difficult to obtain, and in not less than 50 per cent of instances there is a fixed serologic reaction regardless of the treatment given. Several patients who did not respond to nearsphenamine improved greatly under mapharsen therapy. Mapharsen caused complete reversal of the serologic reactions in 44.4 per cent of the authors' eleven cases of early congenital syphilis after only twelve injections (2.5 mg average dose) were given (concurrently with the use of bismuth medication). Further experimentation with larger doses of mapharsen will have to be done before any definite conclusion can be reached about its use in early congenital syphilis.

**Sodium *d*-Lactate in Test for Hepatic Function**—Soffer and his associates differentiated between extrahepatic and hepatic jaundice by determining the utilization of sodium *d*-lactate injected intravenously. The test is dependent essentially on the ability of the intact parenchyma of the liver to convert into glycogen the lactic acid that is circulating in the blood stream. The normal person is capable of utilizing all or almost all the injected *d*-lactate within thirty minutes. None of twenty-five normal persons retained more than 5 mg per hundred cubic centimeters of the injected lactate at the end of half an hour. Of twenty-seven patients with acute diffuse hepatic parenchymal damage with jaundice twenty-six showed retention of 5 mg or more per hundred cubic centimeters of the injected sodium *d*-lactate after thirty minutes. In thirteen instances of jaundice due to extrahepatic obstruction only one showed an abnormal retention of sodium *d*-lactate. The test was used on five patients with diabetes of mild, moderate or severe intensity. The first patient, with a blood sugar value of 150 mg per hundred cubic centimeters during fasting, showed a retention of 5.2 mg per hundred cubic centimeters of lactic acid above the control level. This patient, however, had a large liver, which extended to the level of the umbilicus. The remaining four patients, despite considerable elevation of the blood sugar level, utilized the injected sodium *d*-lactate in a normal fashion. Other hepatic function tests were compared and it was found that in the patients with hepatitis the sodium *d*-lactate and the sodium benzoate tests yielded the greatest incidence of positive results, while the galactose tolerance test and the determination of the ratio of total cholesterol to cholesterol ester showed hepatic damage in only approximately half the instances. For the group of patients with obstructive jaundice the results obtained with the sodium benzoate test were misleading, since in ten instances of proved extrahepatic obstruction with icterus the latter tests yielded seven positive results. In the group of thirteen patients with obstruction, the results with the sodium *d*-lactate test were negative for twelve and the results of the galactose tolerance test were negative for eleven, whereas the determination of the ratio of total cholesterol to cholesterol ester indicated no hepatic damage in nine instances.

**Articular Manifestations of Meningococcic Infections**—Schein presents twenty-three cases and reviews the literature on articular manifestations of meningococcic infections. The study was prompted by a case of meningococcic arthritis

(the patient was seen at Bellevue Hospital after cerebrospinal meningitis) which went on to destroy several joints and produce ankylosis. This was contrary to the author's understanding of the prognosis in this condition. The reports of these cases were selected from the records of the last ten years of Bellevue Hospital (seventeen cases), of Mount Sinai Hospital (four cases) and of private physicians (two cases). All the patients had meningitis at some time during the course of the disease, some had clinical and bacteriologic meningococcemia. The age, sex, severity and duration of the infection and type of treatment (excluding the more recent specific antitoxic antiserum and sulfanilamide) have no influence on the severity, frequency, duration or joints involved in the arthritic lesions. In two cases the articular manifestations preceded the meningitis and in several others the meningeal signs were of such low grade, compared with the accompanying arthritic symptoms, that the diagnosis was confused. In the remaining cases the onset of articular manifestations ranged from the second or third day after full-blown meningitis to as late as four weeks. In one case obvious articular involvement was present only after two and one half months, but since the stupor of the patient was so prolonged and the lesions were so deeply placed this involvement may have been overlooked until then. More than half of the patients showed articular involvement between the fifth and the twelfth day after onset of the general infection. Serum sickness occurred in eleven cases and was questionable in several others, swelling of the joints being the only symptom. Of the joints which became badly destroyed, the elbow was involved in two cases, the hip in two, the wrist in one and the knee in one. Involvement of the knees and hands tended to be more arthritic than arthralgic. The small joints of the hands and feet were attacked in one infant. All the authors who have presented groups of cases of meningococcic arthritis have emphasized the innocuousness of this condition and its fine prognostic import. These and the authors of the textbooks consulted have stated that resolution is the only result to be expected. However, in three cases in this series the joints were permanently destroyed. In addition to these cases the severity of meningococcic invasion of joints is attested by the fact that in six cases aspiration was necessary, in four cases splinting with circular or molded plaster splints was resorted to and in two cases traction was employed to correct flexion deformity of the knee. In only one case was antiserum injected intrarticularly. Three patients died. In none did the arthritis have any relation to the fatal outcome. This confirms the benign prognosis given in the literature as to the outcome of the general infection in patients who show the arthritic complication. The more severe articular manifestations occurred in persons more than 12 years of age, including the cases in which ankylosis resulted and those in which orthopedic treatment was required. In children, then, the outcome of meningococcic arthritis is truly benign, but in adults it is by no means so. In recent cases of meningitis in which antitoxic antiserum (Hoyne) has been given there has been a lower incidence of complications as well as a lower mortality rate than in controlled series in which ordinary antiserum was employed. It is possible that the newer types of treatment, antitoxic antiserum and possibly sulfanilamide, may eliminate meningococcic arthritis, especially in its ankylosing forms.

**Circulation During Pregnancy**—Burwell and his colleagues find that the chief alterations in the circulation of pregnant women are an increased cardiac output per minute, a decrease in the arteriovenous difference, a rise in the pressure in the veins of the lower extremities, an increase in pulse rate and pulse pressure, a loud bruit over the site of the placenta and an increase in the total blood volume. The demonstrated phenomena of the circulation in pregnant women and pregnant animals, plus the available knowledge concerning the structure of the placenta, lead to the conclusion that the changes in the circulation during pregnancy are in the main to be ascribed to two mechanisms: (1) an arteriovenous leak through the placenta and (2) an obstruction to venous return by the enlarged uterus.

**Hypoglycemia**—From his study of the relation of anxiety states and degenerative diseases to hypoglycemia, Quinlan concludes that hypoglycemia may be a transient phenomenon but that there is good reason to believe that it is a constant feature of chronic states which are significant from the standpoint of prophylaxis in cancer, degenerative arthritis and noninfectious cardiovascular disease. Hypoglycemia is pathognomonic of an anxiety state, treatment directed against it primarily is only symptomatic and highly empiric. Anorexia nervosa as a disease is not confined to women, the symptom complex being modified only by the differing gonadal component. It is a redundancy in diagnosis and serves only to confuse a phase of medicine not yet clearly defined and distorts, by exaggeration, one symptom, anorexia, in a train of symptoms more adequately defined under the generic title "anxiety neurosis." An anxiety state is a primary etiologic factor in the degenerative diseases. Endocrine incoordination is its immediate effect. Defective cholesterol catabolism is the result. The prevention of the degenerative diseases lies in the body's capacity completely to excrete or catabolize cholesterol which is in excess of the needs of the body. The problem of medicine, in the face of a cumulatively aging population, is the degenerative diseases.

**Plasma Prothrombin and Partial Hepatectomy**—Warner presents further support for the theory that the liver has an essential part in the manufacture of prothrombin by experiments showing that partial hepatectomy in rats also lowers the

prothrombin level of the plasma. The degree of lowering is somewhat variable from rat to rat, but in many instances the prothrombin falls to extremely low levels during the first twenty-four hours after operation. The prothrombin level returns to normal in the period required for restoration of the liver to normal weight.

**Masked Intermittent Malaria**—Gillick states that the masked intermittent type of malaria may assume the forms of paresthesia, anesthesia, convulsion or paralysis. It may also appear under the guise of edema, hemorrhages from the various mucous outlets of the body or into the skin, diarrhea, dysentery, dyspepsia, bronchitis, pneumonia, appendicitis and the like. Since infections such as the foregoing may obey the law of periodicity, one is not justified in making a diagnosis of malaria unless the condition yields readily to specific therapy or the parasite is found. In most cases of masked malaria the author found the estivo-autumnal parasites. The organism appeared as a small hyaline disk, a ring form within the red blood corpuscle often but few being present. Another feature of the hematologic study of these cases was the marked leukopenia ranging down sometimes to as low as 3,000, and in the differential diagnosis a marked monocytosis was observed which seems to be characteristic of chronic malarial infection in the afebrile period.

 \*Carcinoma of the Cervix Mortality Reduction W Clarkson and A  
 Barker, Petersburg, Va—p 729

**High Speed Roentgenography**—Beese believes that the chief advantage of using condenser discharges in roentgenography is the reduction of blurring caused by motion. This results in increased sharpness of detail. Other desirable features, such as uniformity of film density in successive exposures are obtained because exposure times are eliminated. With a relatively small x-ray transformer and power lines of low capacity, one can do roentgenographic work equivalent to that done with the largest commercial x-ray machines.

**Carcinoma of the Cervix Mortality Reduction**—Clarkson and Barker point out that cancer of the cervix accounts for nearly 20 per cent of all deaths from cancer in women. Their observations agree with those of Norris, who thinks that a cross section of all cases of carcinoma of the cervix will show five year survivals of not more than 10 per cent. When one considers the fact that five year survivals of well over 50 per cent have been reported following proper roentgen treatment of moderately advanced cases, it becomes obvious that the number of deaths can be greatly reduced by the more effective application of treatment methods. Inadequate knowledge of cancer and geographic inertia afflict both the average physician and the general public. Through close cooperation with local medical societies, rotating cancer clinics could carry cancer control to the public and to the physicians. The establishment of cancer clinics would stimulate the demand for specialization in oncology and there is no field of medicine in which intense specialization is more urgently needed.

**Iontophoresis in Arthritis and Vascular Diseases**—Of the 161 individual cases that Kiel treated with acetyl beta methylcholine chloride iontophoresis, seventy-eight were rheumatoid arthritis, twenty-three osteo-arthritis and sixty an assortment of vascular diseases. Forty-three of the seventy-eight patients with rheumatoid arthritis are reported as "completely relieved

(the involved joints function in a normal manner), twenty six as "partially relieved," and nine as having no relief. Any patient reported as partially relieved had a reduction in the swelling of the joints, some relief of the pain, an increase in endurance, lessening of fatigability and a feeling that considerable good had been accomplished by the treatment. Of the twenty-three patients with osteo arthritis four were completely relieved, ten were partially relieved and nine experienced no relief. In the miscellaneous group three of eight patients with thrombo-angitis obliterans were completely relieved or restored to a normal state of health. Of the six patients with gonorrheal arthritis five were completely relieved. These cases in many respects simulate rheumatoid arthritis. Specific therapy was a necessary adjunct to the treatment of these cases. The remainder of the cases are classified as Raynaud's disease, neuritis, bursitis, myositis and traumatic arthritis. Of the total number of patients in this group thirty-five were completely relieved, fourteen were partially relieved and seventeen received no relief. In the rheumatoid group a total of 1,824 treatments were given, representing an average of twenty three treatments for each patient. The osteo arthritic patients received a total of 533 treatments, averaging twenty-three treatments per patient. In the miscellaneous cases 1,525 treatments were given, with an average of about twenty-five treatments each. By far the greater number of treatments was given to those affected with thrombo-angitis obliterans. The least number of treatments with the most encouraging results was given the group of patients with ulcers of the extremities. No patient with a clearcut, uncomplicated ulcer received more than eighteen treatments.

**Improved Method of Lip Fixation**—Ebert and Boyden treated a relatively large number of cases of congenital deformities of the lip by the following technique. Fixation is accomplished by impaling the lip on an ordinary wooden tongue depressor with heavy common bankers' pins. Closure lines having been marked out, the incision is made along these lines. The authors prefer to employ a new sterile razor blade held in a curved hemostat. Approximation of the segments of the lip is rendered more facile and exact by manipulation of the free ends of the tongue depressors. The edges are brought into place and held there by an assistant while the operator places the sutures. The cosmetic and functional results in the cases in which operation was performed were exceptionally satisfactory.

**Employment of Diabetic Persons**—Lawrence and Madders consider the discriminating attitude of employers against diabetic employees as unfair and unjust. This attitude is a survival of preinsulin days, when ill health and early death of the diabetic employee were the rule. In an effort to remedy this handicap of the diabetic employee the authors studied 100 employed diabetic persons. This investigation showed that 77 per cent lost no time from work because of their diabetes after the initial stabilization of treatment, the figure is 85 per cent if the ultimate stabilization on insulin of another 8 per cent originally treated by diet alone is included. About 55 per cent of the employees lost some time because of illnesses unconnected with their diabetes. The survey has no statistical accuracy but it does show that most diabetic persons treated adequately are good employees from the point of view of health. It is hoped that the widespread prejudice against their employment may be removed.

**Acute Anterior Poliomyelitis**—Four cases of acute anterior poliomyelitis occurring on the same day in a boys' school are reported by Barber. Since no other cases occurred in this school, a close analysis was made of the daily habits and lives of these four boys. Cases did appear later in the village and two of them occurred in the family of one of the maids employed by and living in the same house of the school that the four boys lived in. These cases were attributed to the maid having carried the infection home. As she was in the house for the rest of the term and no further cases occurred there, and as one attempt to infect a monkey from her proved negative, there is no actual evidence that she was a carrier. The house in which the four boys lived has separate feeding arrangements and a separate domestic staff from the rest of the school. Only two of the boys slept in the same dormitory. The other two were in different dormitories, and each was unconnected with the others in any activity. In the house-room all four were in different corners and one of them was present only occasionally as a house prefect. In the school all four were well scattered, being in different classes and other categories. The only common factors appeared to be the same feeding arrangements and contact with the same domestic staff. The only connection with food was that strawberries, obtained from two farms (one of them at Halstead which had been affected) were served only in the house in which the affected boys lived. If it is conceivable that the virus should be present in such contamination, accident would no doubt account for its being ingested by only a small number of those eating the fruit. The simultaneous onset certainly resembles a food-poisoning outbreak rather than an epidemic spread by droplet infection. This possible route of infection has already been discussed by Kling in Sweden on

rather different evidence. The present account is given with the object of suggesting an additional line of investigation.

**Sulfapyridine in Gonorrhea**—Batchelor and his co-workers used sulfapyridine in the treatment of 102 cases of gonorrhea. Apparent cures were obtained in more than 91 per cent of the patients. Toxic effects were encountered in 29 per cent. The commonest manifestations of intolerance were nausea and headache, and in most instances these symptoms were slight and the patients were able to continue with the treatment in reduced dosage. In the successful male cases, clinical cure was attained in less than a week. In the successful female cases, signs which might be interpreted as denoting infection persisted for two weeks but gonococci disappeared from the smears almost as quickly as in the male cases (less than three days). Thus in the early cases the gonococcal infection was cured before the time when the disabling complications, epididymitis or salpingitis, are to be expected. Also cure was effected without the time-consuming and often badly applied local irrigation treatment. In the future the fear of stricture of the urethra, with its ever present threat of retention or extravasation of urine, should be much less and the depressing picture of the chronic pelvic invalid should be less often encountered among the habitués of spas and health resorts. Above all, the possibility of spread of the disease should be greatly reduced, since the period of infectivity is shortened.

Anemia in Pregnant and Parturient Women J. J. C. Pietersen—p. 848

**Treatment of Malarial Splenomegalies by Ascoli Method**—Froilano de Mello used the method of Ascoli in the treatment of twenty cases of malarial splenomegaly. The method consists in the daily intravenous injection of increasing doses of epinephrine. The beginning dose is 0.01 mg and it is increased daily by 0.1 mg until 0.1 mg is reached. This last dose (0.1 mg) is continued for twenty days. The reduction of the spleen, in the author's experience, has rarely been absolute by the Ascoli method alone. In the majority of cases it has reached about 50 per cent of the initial hypertrophy. The combination of Ascoli's method with specific antimalarial chemotherapy has given in one case unexpectedly good results. But more observations are required to give value to such combined treatment. In some patients the amelioration in the general state is more pronounced than the reduction of the spleen. The method of Ascoli does not prevent relapses. The number of injections and the unpleasant, sometimes serious, symptoms (bodily sensation of heat, decrease in pulse rate, palpitation, abdominal cramps, tremors, cardiac arrhythmia, giddiness and the like) observed do not recommend such a method as an advisable routine treatment, at least among the malarial folk in rural India. However, the use of such a method in hospital practice should be encouraged, provided the unpleasant reactions are avoided either by a less diluted dosage or by some process of desensitization requiring further research.

 New Method of Treatment of Chronic Constipation B. P. Kouchelevsky and E. I. Milutine—p. 970

**Treatment of Gastric and Duodenal Ulcer**—Okada and Doi prepared an extract from the mucosa of the stomach and another one from the mucosa of the duodenum. The two preparations, which contain all the essential parts of the two mucosae, have a regenerating effect which is specific for the mucosae of the stomach and the duodenum respectively. The authors administered the preparations by intravenous injection in sixty cases. Discussing the mode of application, they say that the patients who were treated at the hospital were usually given one injection daily. The initial dose is usually 0.5 cc., but this quantity is gradually increased. After about thirty injections have been given the treatment is usually terminated, but some patients require a more, others a less prolonged treatment. Toward the end, some patients are treated with diminishing doses. It seems that at the beginning the best dose is 2 cc. If after five injections of this dose the symptoms diminish, the same dose is repeated, if not it is increased to 3 cc. Occasionally 4 or 5 cc. may be administered. The authors say that the results obtained with this treatment are highly satisfactory. Of the eighteen patients with gastric ulcer who were treated with extract of the gastric mucosa, fourteen were cured and four were improved. Of four patients with gastric ulcer who were treated with duodenal extract, two were cured and two improved. Of thirty-six patients with duodenal ulcer who were given duodenal extract thirty were cured and four improved, and of the six patients with duodenal ulcer who were treated with the extract of gastric mucosa one was cured and four were improved. The late results seem to be favorable in about two thirds of the cases, however, additional observations will be necessary for a final evaluation.

**Radicular Paralysis of Obstetric Origin**—The radicular paralyzes that are the subject of this paper by Duhem and his associates are generally caused either by obstetric traumatism in the course of delivery or by accidental traumatism of the shoulder and neck during life. It is generally considered that three types of factors are likely to cause the appearance of radicular paralyzes: (1) osseous lesions on the superior extremity of the humerus, (2) lesions of the shoulder joint and (3) direct lesions of the motor nerves of the cervical region (brachial or cervical plexus). All these lesions can be produced in the course of difficult labor with or without the application of forceps, in normal deliveries they are rare but not impossible. The determination as to which of the three possible causal factors is responsible in an individual case is usually not difficult. If there is a doubt as to whether a voluminous hematoma or a deformation of the epiphyseal region is responsible, roentgenoscopy will reveal it. The clinical aspects, the paralysis and electrodiagnosis will disclose whether a nervous lesion exists. Electrodiagnosis is resorted to when roentgenoscopy has demonstrated that osseous or articular lesions are absent. To be sure, the nervous lesions do not manifest themselves immediately by a reaction of degeneration, a certain time is necessary, which is rarely less than two weeks. The diagnosis may be complicated by the fact that the lesions are multiple. Distortions or epiphyseal detachments may be accompanied by vascular

lesions (lacerations and the like), which may be the cause of ischemic troubles and these in turn of secondary paralyzes. In view of the complex nature of some of the lesions (osseous, tendinous, nervous and so on), it has been suggested that the general and inclusive term of "traumatism of the shoulder of the newborn" be applied. The authors point out that the complex lesions result in the formation of perinervous and perivascular cicatricial tissues, which are the principal factors that prevent a spontaneous cure. This is why they utilize the solvent action of potassium iodide, which is introduced in situ by means of galvanic current. It was Leduc who gave them this idea of the solvent action of the iodine ion. This treatment must be employed as early as possible, particularly in case of nervous lesions, for the functional results become problematic if the nerve fibers have had time to degenerate. The authors discuss the sites of application of the electrodes (Erb's point and axilla) and state that they employ a 1 per cent solution of potassium iodide. The applications last thirty minutes and are made with an intensity of 4 or 5 milliamperes. The authors begin with a series of twenty treatments, the first seven or eight of which are given daily. After an interval of three or four weeks the treatments are resumed. In most cases a second and third series of treatments are necessary and in grave cases the treatments may have to be continued for eighteen months or two years. In answer to the question whether excitomotor current should be applied to the paralyzed muscles, the authors say that this depends on the electrical reactions. If from the beginning no reactions of degeneration are observed, the treatment with potassium iodide rapidly effects cure and the excitomotor currents may be employed to give more force to the recuperated muscles. In case of partial degeneration it is necessary to await amelioration, because if not employed with great care the excitomotor current may be more harmful than beneficial. The authors advise against the use of the faradic current because it is too brutal. In the conclusion they stress the necessity of persistence on the part of the physical therapist in cases of radicular paralysis of obstetric origin.

 Two Tests of Dehydration in Surgical Patients J. Bollin—p. 1763

**Arteriolar Spasm in Cardiac Insufficiency**—Warenbourg and his associates point out that the heart and the peripheral circulation are so intimately related that failure of the one leads always to considerable disturbances in the function of the other. They studied the peripheral circulation of sixty-four patients with heart disease. On the basis of the roentgenologic and electrocardiographic studies the sixty-four patients could be grouped into three categories. The first group of eighteen patients presented no signs of cardiac decompensation. In the second group of twenty-nine patients are classed those with hyposystole presenting signs of ventricular insufficiency. Seventeen patients with complete asystole made up the third group. To explore the arteriocapillary circulation the authors subjected these groups of patients to three different tests: (1) to hot and cold baths of the forearm, (2) to intradermal histamine tests and (3) to intradermal tests with acetylcholine. On the basis of these studies on the peripheral circulation of patients with heart disease the authors conclude that arteriolar spasms frequently exist in decompensated cardiopathies. In the sphere of the capillary circulation this arteriolar hypertension is accompanied frequently by spasm or perhaps by dilatation. To counteract the arteriolar barrier and assist the cardiac function, the authors regard it advisable to employ, in addition to the classic cardiotonic therapy, vasodilative drugs, among which the papaverine extracts of opium appear to furnish the best results.

- Tuberculosis and Renaissance of Medicine J. Troissier—p. 1793  
 \*Treatment of Extrasphinctral Anal Fistulas Method of Elastic Ligation P. Rochet and M. Violet—p. 1798

**Treatment of Extrasphinctral Anal Fistulas**—Rochet and Violet call attention to the difficulties that are encountered in the treatment of anal fistulas, to the technical difficulties, to the frequency of relapses and to the risk of incontinence follow

ing section of the anal sphincter in extrasphincteral fistulas. The frequency of relapses has led many surgeons to suspect that the tuberculous origin is responsible for this development toward chronicity. Whereas numerous authors maintain that anal fistulas are always tuberculous, other observers regard the tuberculous origin of anal fistulas as comparatively rare. In the second part of this report the authors describe the formation of an extrasphincteral anal fistula from a submucous abscess and show the necessity of finding a procedure which drains the fistula in its entire course and which sections the interposed tissues without lesion of the sphincter. Such a procedure was known in the time of Hippocrates under the term of "apolinosis." The elastic ligature, a modification of the ancient method, was first described in 1862. Its mode of action has been defined as follows: A rubber drain by its elastic quality effects a uniform and constant compression on the surrounding tissues and destroys, layer after layer, by progressive ulceration, it does not cut but ulcerates, it does not remove but destroys, flattening and obliterating the vessels before it divides them. The most interesting aspect of this slow and continuous section is the penetration of the anal sphincter: the latter is sectioned in its entire thickness, without there ever being a complete solution of the continuity. The intervention is made under spinal anesthesia. Anal dilation is usually superfluous, since the sphincteral relaxation caused by the spinal anesthesia is generally sufficient. The injection of a solution of methylene blue into the cutaneous orifice greatly facilitates the intervention, because it makes it possible to follow the fistulous passage and may even disclose a microscopic rectal perforation. It is necessary to excise the fistulous passage that is indicated by the methylene blue stain. The elastic ligature is put in place by introducing it through the cutaneous wound and letting it emerge again through the anal orifice. It consists of a rubber drain, 5 mm in diameter. The intervention is terminated by placing a wick in the excised region. The authors accompany the description of the intervention by diagrams. Discussing the postoperative course, they say that the rubber drain falls out spontaneously between the fifth and the twelfth day. The time required for total cicatrization depends on the extent of the fistulous passage, it varies between twelve and forty days. The authors say that since 1935 they had occasion to treat twenty-six extrasphincteral fistulas. In more than half of the cases a previous operation had been followed by relapse. The authors did not have a single failure. All the reexamined patients were free from relapse of any kind. The condition of the anal sphincter was always excellent. The authors stress the simplicity of the method, which employs the elastic ligature, and recommend its use to those who regard the treatment of anal fistulas as a hopeless enterprise.

**Spleen and Lipoid Exchange.**—Roseblum and Sapiro state that the spleen is closely connected with a number of glands of internal secretion. After citing evidence of its connection with the thyroid and the genital glands they show that the lipoid (cholesterol) exchange is largely dependent on the hormone of the spleen. They investigated the status of cholesteremia in various disorders with splenic involvement because they reasoned that, if the hormone of the spleen really influences cholesteremia, a study of the modifications of cholesteremia in diseases of the spleen might be helpful in finding a method for the functional diagnosis of these disorders. To determine the influence of the splenic hormone on cholesteremia in various disorders they resorted to the intravenous injection of extract of hog spleen. Before this injection is made and while the patient is still fasting, a specimen of blood is withdrawn and these withdrawals are repeated at hourly intervals

for five hours after the injection. The cholesterol content of the specimens is determined according to the method of Smirnova and of Engelhardt. The authors made this test on twenty-one patients. In summarizing their results they state that the injection of splenic extract provokes an increase in the cholesteremia. The evolution of myelosis and erythrocytosis is accompanied by a low cholesteremia curve and these patients do not react to the introduction of extract of hog spleen by an augmentation in cholesterol. However, after an efficient roentgen therapy of myelosis, extract of hog spleen produces an increase in cholesteremia. In diseases of the liver accompanied by grave impairment of the parenchyma the cholesteremia curve is low and it does not react to the administration of extract of hog spleen. The authors conclude that the increase of cholesteremia under the influence of splenic extract in healthy persons, and the absence of this phenomenon in splenomegaly disorders, raises the question whether in the future this method may not serve as a functional test for the liver.

\*Question of Gonotoxic Icterus. M Oppenheim and A Fessler—p 1299

**"Gonotoxic Icterus"**—Oppenheim and Fessler direct attention to a report by Popper and Wiedmann in which it was demonstrated that in recent years catarrhal icterus has been comparatively frequent in the course of gonorrhea. Popper and Wiedmann were of the opinion that there was a causal connection between impairment of the liver and gonorrhea, assuming that the icterus was produced by toxins of the gonococci and consequently designating this icterus as "gonotoxic icterus", to be sure, they emphasize that another factor, such as an alimentary intoxication or vaccine therapy, is usually necessary for the manifestation of the hepatic impairment, but they regard as unlikely a harmful effect of acriflavine hydrochloride. Oppenheim and Fessler, on the other hand, deny that the icterus which develops in the course of gonorrhea is due to hepatic impairment by the toxins of the gonococcus. They are of the opinion that this icterus, if it cannot be traced to an alimentary intoxication, is the result of intolerance toward the mode of treatment (intravenous injection of acridine dyes, vaccine therapy or fever therapy with bacterial proteins). They base this opinion on the fact that the literature contains only few reports about icterus in gonorrhea, that they themselves never observed an appreciable number, although their annual material consists of from 700 to 800 cases, and that, even in cases of the severest septic complications of gonorrhea, icterus is rare. In contradistinction to Popper and Wiedmann, the authors are of the opinion that treatment with acriflavine hydrochloride is an important factor in the development of so-called gonotoxic icterus. That the incidence of this type of icterus has so greatly increased in recent years they ascribe to the fact that parenteral therapy has largely replaced the local treatment. They detected three cases of icterus that had been treated elsewhere either with acriflavine hydrochloride or with vaccine. They were not able to obtain information about the dosage, but they think that hepatic impairment develops without excessive doses, since hypersensitivity is involved.

\*Local Anesthesia in Treatment of Traumatic Arthritis. G Muzzarelli—p 881

**Traumatic Arthritis.**—Muzzarelli reports satisfactory results from local periarticular anesthesia in the treatment of posttraumatic arthritis, especially of the knee and elbow joints. The treatment consists in administration of three or four injections

of from 5 to 10 cc of a 1 per cent solution of procaine hydrochloride given in the periarticular space of the knee joint or in the epitrochlear, epicondylar and olecranal regions of the elbow with intervals of two weeks between injections. Immediately after the injection is made the patient complains of a tolerable transient local burning sensation. Movement, flexion and extension become immediately normal. The patients can go up and down stairs and walk with confidence. If there is an overlooked partial fracture the functional results are not the same as those obtained in simple traumatic arthritis, in which pain either disappears after the first injection or reappears greatly diminished in intensity one week after the injection and then disappears in the course of the treatment. The treatment is complemented by local application of heat and physical exercise by the patient. It is indicated in cases of articular trauma with slight internal or external lesions or after prolonged immobilization of a joint in fractures. It is valuable in detecting simulators. Five cases are reported, in all of which satisfactory results were obtained.

\*Influence of Intravenous Epinephrine Therapy on Metabolism in Malaria N. Bonarrigo—p. 1229

Experimental Reticulosarcoma from Thorotrast Case O. Onufrio—p. 1245

**Influence of Epinephrine on Metabolism in Malaria**—In fourteen cases of chronic malaria with splenomegaly, Bonarrigo observed the behavior of the metabolism before and after making tolerance tests of dextrose and stearic acid, which he did before and after the administration of the intravenous epinephrine treatment for malaria. The tolerance tests were made after oral administration of either 30 Gm of dextrose or 20 Gm of stearic acid. The author found that the general metabolism is disturbed in malaria. The patients suffer, while fasting, from hypoglycemia (and in rare cases from hyperglycemia) and also from hyperketonuria regardless of the fact that they are fed on a diet rich in carbohydrates. There is a poor utilization of dextrose as shown by the crises of hypoglycemia late in the course of the dextrose tolerance test. There is also an abundant elimination of ketone bodies through the urine after the tolerance test of stearic acid. When the tests are repeated after completion of the epinephrine treatment the results show a better utilization of dextrose by the body and a diminished elimination of ketone bodies through the urine in comparison to that which takes place when the tests are performed before the administration of the epinephrine. According to the author the metabolic disturbances in malaria are due partly to malarial anatomopathologic lesions of the liver and partly to functional disturbances of the hypophysis by which the neurosympathetic equilibrium is ruptured with consequent disturbances of the correlations between endocrine glands, diminished secretion of insulin and lowering of the tonus of the spleen. Epinephrine, administered by the intravenous route, normalizes or greatly reduces the size of the spleen. The neurosympathetic disorder and the correlations of endocrine glands are controlled by the treatment by which the production of insulin increases, the spleen maintains a normal tonus and the general metabolism becomes normal. On completion of the treatment splenomegaly permanently disappeared and the crisis of the blood, elimination of ketone bodies through the urine and general condition of the patient were either normal or greatly improved. The results of the treatment are permanent.

**Influenzal Otitis**—Pirodda attempted to produce experimental influenza in ferrets by inoculating them with the pathologic material from the middle ear of four patients suffering from influenzal otitis. The otitis developed early in the course of influenza and was grave, hemorrhagic and with mastoid

complications in two cases. It developed during convalescence from influenza and was benign in two cases. In all cases the pathologic material was taken from the middle ear after paracentesis and disinfection of the auditory canal. With a portion of the material, cultures in blood agar were prepared, and another portion of the material was inoculated into ferrets. *Haemophilus influenzae* could not be isolated from the cultures. The ferrets did not develop influenza. The author therefore concludes that influenzal otitis is caused by the influenzal filtrable virus alone without interference of the influenzal bacilli. Experimental influenza develops from inoculation of pathologic material which contains both the filtrable virus and *Haemophilus influenzae* in synergy. It does not develop when the inoculated material contains either etiologic factor alone.

Microscopic Studies of Fractured Neck of Femur Which Has Been Operated on F. Felsenreich—p. 96

Experimental Study of Effect of Contrast Medium (Roentgenologic) on Narcosis N. Sugihara—p. 135

\*Relationship of Cholelithiasis to Primary Cancer of the Gallbladder W. F. Bottiger—p. 146

**Brown Tumors and Bony Cysts**—According to Puhl, bony cysts are benign mesenchymal tumors with moderate tendency to growth and a poor blood supply. The latter fact explains the breaking down of its tissue and the rapid formation of cavities. The formation of capillaries bears an embryonal character and attempts to provide the blood supply for mesenchymal tissue, which may easily be confused with granulation tissue. If the process is inadequate, extensive breaking down of tissue leads to new formation of large cavernous spaces the walls of which are made up of mesenchyma of its more mature type. These observations contradict the concept of a hematoma or of granulation tissue as the underlying character of cystic formation. Giant cell tumor is a benign mesenchymal neoplasm with a greater tendency to growth and richer cellular structure. The nourishment of its mesenchymal tissue depends on the blood spaces, which are formed with the aid of greatly increased giant cells. In this manner the nutrition of the tumor is easily provided for and breaking down of the mesenchyma takes place rarely. The angiocavernous blood spaces may likewise lead here to the formation of one or several cysts. Fibrous tissue, osteoid tissue and bone formation, as well as cartilaginous structures, belong to the typical maturation manifestations of the mesenchyma and are therefore to be regarded as neoplastic tissues. The same applies to the cavernous spaces and their variously constructed walls, which have nothing in common with normal blood vessel walls. The author regards a central fibroma as a healed form of a genuine cyst. According to the same concept they represent, very much like certain chondromas, osteomas, and angiomas, matured mesenchymal hematoma, with a slight tendency to growth. The possibility of a secondary malignant degeneration of a giant cell tumor has been definitely established. It is to be expected that other types of osteogenic sarcoma will be found even though the osteoid, chondroid and bony structures suggest a benign tumor. Many errors arise from the fact that a characteristic representative of a primary osteogenic sarcoma, described by Geschickter and Copeland as osteolytic, resembles closely, aside from its cellular polymorphism, the giant cell tumor. The author considers this type of sarcoma a representative of the malignant group of primary mesenchymal bone neoplasm. He considers it most likely that the other forms of osteogenic sarcoma develop from mesenchymal tissue. The formation of primary bony tumors is therefore regarded as a group of benign and malignant mesenchymal neoplasms arising on a dysontogenic basis. A relatively small group of neoplasms arising from the basis of regeneration are represented by tumors arising from a callus, the radium sarcoma and the Paget variety.

**Cholelithiasis and Primary Cancer of Gallbladder**—According to Bottiger the etiologic role of gallstones in the causation of the primary cancer of the gallbladder is demonstrated by the striking preponderance of primary carcinoma of the gallbladder in women. Eighty per cent of primary gall bladder carcinoma is associated with stones, whereas metastatic

carcinoma of the bladder is associated in only 15 per cent with stones. The author demonstrates statistically that the relationship of secondary gallbladder carcinoma in men and women is the reverse of that which appears in primary carcinoma. It was possible experimentally to produce an adenocarcinoma through gallstones. The author believes that it is not the mechanical irritation of the concretions that acts as a direct cause of cancer formation in the gallbladder, but rather the chronic regenerative process accompanying it coinciding with the age during which the organism displays a general disposition to cancer formation.

#### Modification of Schick Reaction by Vitamin C—

According to Schwartz and Stockebrand it is not definitely decided as yet whether the administration of adrenal cortex extract and ascorbic acid produces a decided change in the course of diphtheria. Although it is possible to protect guinea pigs against fatal doses of diphtheria toxin, the results obtained in human subjects are not convincing, for the modification of the toxic symptoms produced by the diphtheria toxin is only slight and it seems unjustified to designate ascorbic acid as true antitoxin. To be sure, it cannot be denied that vitamin C and adrenal cortex extract have a certain significance for the defense against infections. In every infectious disease a vitamin C deficit develops and counteracting this deficit has a favorable effect on the course of the disease. In order to determine to what extent variations in the vitamin C content of the organism play a part in the changing susceptibility to diphtheria, the authors made Schick tests and studied the vitamin C elimination in the urine of twenty-five children, some of whom were healthy and some were convalescents from tuberculosis and scarlet fever. A table indicates that twenty-one children had a positive and four a negative Schick reaction. The latter four did not show an especially high vitamin C elimination in the urine. The twenty-one children with the positive Schick reaction were subjected to oral treatment with vitamin C and then a second Schick test was made. It was found that the administration of vitamin C did not effect a weakening in the Schick reaction, however, the susceptibility toward the nonspecific protein component of the diphtheria toxin was noticeably reduced.

Animal Experiments on Distribution of Injected Soluble Radium in Various Tissues of Body F Daels H Fajerman, van de Putte and Van Hove—p 545

**Radium Therapy of Hemangiomas**—Baensch discusses the histologic structure of hemangiomas, pointing out that the structure determines the selection of the technic of the radium therapy. Describing the histologic aspects of simple or plexiform angioma, he shows that especially during the first months of life these hemangiomas spread rapidly. Growths which at birth are the size of a lentil may extend over an area four or five times as large at the end of two months. Another form, the cavernous angiomas, go much deeper than does the simple type and they appear chiefly in the region of the skull, more especially

in the so called embryonal clefts, that is, on the inner canthus, the upper lip and below the ear. It is important to know that such cavernous hemangiomas are generally not limited to the visible and palpable surfaces but may extend through the bone clefts to the deeper layers and even into the cranium. The third type of vascular tumor discussed by the author is the angio-plastic sarcoma. In contradistinction to the first two types, which are always benign, this form may become malignant. The author mentions three methods of radium therapy. The first one, the application of pastes that contain radon, is suited only for simple, superficial angiomas. Moreover, it has the disadvantage that it requires much time. The second form of treatment, which employs the moulage method, likewise requires considerable time. The author employed a more rapid method, the introduction of radium into the tissues by means of needles. The needles contain 1, 2 or 4 mg of radium, and filtration is effected by means of platinum-iridium. In nurslings (of the fifth month) the author introduces the needles under a short ethyl chloride anesthetic, in older children or adults, under local anesthesia. The size of the needles is adapted to the extent of the hemangioma, and the needles are distributed in such a manner that about 1 mg is introduced per cubic centimeter. The sites of insertion are selected so as to insure favorable cosmetic results, for instance, in the region of the lips and cheeks, the needles are introduced by way of the oral mucosa. In case of large angiomas the radium puncture can be combined with the moulage method. After the first radium puncture of two days' duration the patient is discharged, for the irradiation is repeated only after at least two or three months has elapsed. It has been observed that during this time the retrogressive process continues. In order to avoid disappointment, attention should be called to the slowness of the process. The author employed this method with good results in 230 cases. In 2 per cent of the cases superficial necroses developed, but these healed with smooth scars. Injurious effects of the rays were not observed. Follow-up examinations, extending over six or seven years, never disclosed damage to adjoining organs such as the eyes or the bones. The author gives brief histories of several cases and reproduces photographs illustrating the good results.

**Action on Metabolism of Coffee With and Without Caffeine**—After calling attention to the growing consumption of coffee, from which the caffeine has been extracted, Steudel admits that the pharmacologic effects of caffeine and the fact that they are frequently undesirable cannot be denied. However, the experiments which were carried out to demonstrate the actions of caffeine were often made with large quantities of caffeine that are never consumed under ordinary conditions. The author studied the behavior of ordinary coffee and of caffeine-free coffee in artificial digestion and then he made experiments on dogs. The artificial digestion experiments proved that coffee, when used in normal quantities, does not disturb the digestive processes. These experiments disclosed no differences between coffee which contained caffeine and the coffee from which the caffeine had been extracted. When coffee was given to dogs in physiologic quantities it was found that the elimination of nitrogen in the urine was reduced, irrespective of whether the coffee infusion had been made with ordinary coffee or with coffee from which the caffeine had been extracted. When the coffee was left out of the diet, the elimination of nitrogen in the urine increased again. The quantity of nitrogen, by which the urinary secretion is reduced, does not appear in the feces. In what form the nitrogen is retained in the organism during the time of the administration of the coffee the author

is unable to state with certainty. He says that during the fifty-nine days when the animals were given coffee they lost some weight. Nevertheless it must be concluded that coffee contains substances which act on the nitrogen exchange by effecting retention. That this effect is due to a specific action of the coffee is proved by the fact that when substitutes in the form of infusions of roasted, malted grains were used there was no change in the elimination of nitrogen in the urine.

 Basal Metabolism in Hypertonia E Ya Reznitskaya and P Ya Spivak —p 1410

**Basal Metabolism in Hypertonia**—On the basis of their studies of basal metabolism in 620 cases of hypertension, Reznitskaya and Spivak conclude that no relationship exists between the height of maximal pressure and the height of basal metabolism. The gravity of the clinical manifestations of hypertensive disease does not necessarily depend on the height of the maximal pressure. They found that basal metabolism in cases of compensation and of mild decompensation is normal or near normal, even in the presence of severe hypertension. The thyrogenous form of hypertension, however, is accompanied as a rule by increased basal metabolism. Insignificant alterations in the basal metabolic rate were present in hypophysisal types, such as Cushing's disease, in obesity and in hypertomas of genital origin. Basal metabolic rate was normal in hypertension of pancreatic origin (accompanying mild types of diabetes). In fourteen cases of hypertension of the arteriosclerotic type nine showed normal metabolic rates and five insignificant deviations from the normal. In a group of twelve patients with nephritic hypertension, four had a considerable increase in the basal metabolic rate while eight had a rate close to normal. The authors conclude that determinations of the basal metabolic rate do not aid in the differential diagnosis of the type of hypertension.

 Arrest of Hemorrhage from Hand Forearm or Upper Arm by Injured Person Himself and by Others W R H Kranenburg and O Bánki —p 5390

**Actinomycosis**—Ening surveys seventy-nine cases of actinomycosis which were treated at the surgical clinic in Groningen in the course of the last thirty years. There were forty-six cases with localization in the region of the neck and jaw, thirty-one cases with abdominal localization and two cases with thoracic and pulmonary localization. Follow-up examinations were possible in most cases and these disclosed that in actinomycosis of the neck and jaw there were 88 per cent of recoveries and in abdominal lesions 28.5 per cent of cures. After discussing the role of occupation in the development of actinomycosis the author takes up the port of entry, the diagnosis and the treatment and cites noteworthy case reports. About the treatment he says that the superficial processes often react favorably to roentgen irradiations. Extensive surgery is now largely dispensed with, particularly in cases of actinomycosis of the neck and jaw, the more so since the cosmetic results are usually not good. Even in abdominal actinomycosis the results of surgical treatment are not satisfactory. The author thinks that roentgen irradiation combined with moderate surgical treatment is the best method. These measures can be sustained by potassium iodide given orally, by fuadin injections and blood transfusions. In appropriate cases the gold-vaccine treatment of Neuber can be considered.

**Diffuse Postabortal Peritonitis**—In attempting to establish the principles of the treatment of diffuse postabortal peritonitis, Holst collected a material of 176 cases, 100 of which had been treated by laparotomy and drainage. A comparison between this surgical method and the radical operation shows that the first method is to be preferred, because the general condition is frequently so poor that the patient will not tolerate a more complicated intervention and also because functionally important organs are thus saved. To be sure, the results that have been obtained with this method, so far, are not encouraging, only twenty of 100 patients have survived. This is chiefly due to the fact that the operation was performed too late, in order to improve the results it is necessary to intervene at an early stage. Consequently an operation is indicated not only in the presence of clear signs of diffuse peritonitis but also when there are symptoms which indicate that the infection is spreading to the abdomen, particularly when they increase rather than subside or when the general condition is impaired to such an extent that a severe infection must be suspected.

- \*Action of Streptomide on Leukocytes E Bruun —p 1273

**Action of Sulfanilamide on Leukocytes**—Bruun concludes that in addition to the toxic effects of sulfanilamide preparations previously described there is undoubtedly an action on the white blood picture with depression of the leukocyte count selectively affecting the granulocytes. It may be rapid and intensive, as a rule disappears at once when the preparation is discontinued, seems to be without fatal results and is assumed to be due to a toxic destructive action on the leukocytes in the peripheral blood. The acute lethal agranulocytosis observed in rare cases after the administration of large amounts of sulfanilamide (from 40 to 60 Gm) and dosage for over three weeks, is accompanied by marked changes in the bone marrow, it may depend on ordinary overdosage of the substance or perhaps on an idiosyncrasy. The author reports twenty-three cases of scarlet fever, seventeen of which were treated with from 1 to 36 Gm of sulfanilamide daily for not more than five days, of these thirteen (85 per cent) showed a reduction in the granulocyte count. The course in scarlet fever was apparently not influenced by the treatment, there was usually a lytic fall in temperature and the duration of the fever did not differ in the patients treated with sulfanilamide and those treated without sulfanilamide.

### Speech Defects in Relation to Physical Condition and Health

H J HELTMAN, A B, AND L M HICKERNELL, M D

SYRACUSE, N Y

For many years physicians as well as those who specialize in speech correction have been conscious of the somatic aspects of speech defects. Often physicians undertake to treat such disorders on the assumption that the establishment of normal health per se will result in the acquisition of normal speech. Conversely, there are speech correctionists who attack this problem with complete lack of understanding that there may be organic pathologic changes which cannot be corrected through the efforts of the speech therapist alone. Qualified practitioners in both fields, however, are aware that either or both of these factors may be the root of the trouble. Both physical and mental health are essential for proper speech, and in those who have speech defects reeducation of the speech processes after anatomic defects have been corrected is the only sound procedure.

Effective therapy cannot be accomplished until accurate information concerning the patient's somatic condition is available. The Student Health Service and the School of Speech at Syracuse University have therefore combined facilities in an attempt to diagnose each student's actual difficulty. Only after such a procedure can correct treatment be instituted to provide the student handicapped by a speech defect with the best possible chance for improvement or cure.

The Student Health Service is adequately equipped for a complete diagnostic survey of each individual. Audiometric examinations and otolaryngologic studies are made as a routine on all students known to have defects of either speech or hearing. The resident in otolaryngology at the University Hospital makes these examinations, so that physical examination of the vocal tract and ears as well as hearing tests are made by a qualified physician.<sup>1</sup> In addition to this, records in the Student Health Office contain all the necessary information concerning each student's health and general physi-

cal condition. These records are of course available during the diagnostic survey and are useful in connection with the consideration of therapy.

Cases of early involvement observed during this study were called to our attention primarily by obvious difficulties in speech. A small number of persons with spasticity were discovered during the routine physical examination made at entrance. These were referred to the speech department for corrective attention. The speech department also picked out from its classes persons with dyslalia and referred them to the health service for examination. Though it is too early to give any detailed report of the examinations, some data have already accumulated which are interesting if not yet significant. One student insisted that he was "not very deaf" but showed more than 80 per cent loss in each ear. On the other hand a student who had been receiving corrective treatment over a period of three years for dyslalia and who constantly insisted that he had a great deal of difficulty in hearing teachers in class was found to have a hearing loss of only 12 per cent in one ear and of 15 per cent in the other.

Students with dysphonia are given a complete otolaryngologic diagnostic survey. Hearing tests are also performed in the routine manner. If the vocal defect is found to lack an anatomic basis it is considered as being of functional origin. In cases of functional dysphonia it is necessary only to apply an appropriate reeducational technic to remedy the difficulty. However, in cases of hysterical dysphonia psychiatric treatment is clearly indicated. When there is a definite pathologic basis for the dysphonia, anatomic correction may be necessary. Collateral reeducational therapy may or may not be indicated. When such therapy is indicated, the specialist in speech proceeds toward this under the immediate direction of the otolaryngologist.

To extend the effectiveness of this cooperative project the general health examination of this semester's entering class included complete

<sup>1</sup>From the School of Speech and the Student Health Service, Syracuse University.

<sup>2</sup>In some speech clinics examination of the larynx, nose and ears is made by a specialist in speech who may not be a qualified physician.

audiometric determinations and speech tests. The problems and defects disclosed by these tests are enabling the university to take the initiative in bringing to the attention of students thus handicapped the facilities for diagnostic and corrective measures within the Student

Health Service and the Department of Speech. The diagnostic surveys by the otolaryngologists are still being conducted. Any surgical treatment found indicated continues to be referred as in the past to qualified physicians in the appropriate fields.

## Comments and Reviews

### THE ART OF DIAGNOSIS

*Abridgment of a lecture by Frank Cook, Esq., F.R.C.S., published in Guy's Hospital Gazette, Oct. 22, 1938*

Since it falls to my lot to examine a large number of candidates in their finals, I wish to refer particularly to the clinical examinations to which I assure you considerable importance is attached. The average candidate, having examined the patient, starts off in this manner: "The patient's age is 25, she had measles as a child, she has not had scarlet fever, she has six teeth missing, her tonsils were removed at the age of 10, her last menstrual period was October 19," and so on. He fondly believes there is one answer and one answer only to the clinical problem before him. Therein lies a paradox: the more discursive the medical man of today, the more does he hope to find a brief and comprehensive label in the end. As if any one could sum up in words that infinitely complex organism a human being affected by pathologic processes, and place the whole in a nutshell. This is the main point of my discourse, but let us return to the candidate. To him I say: "You are conscientious, your teachers have taught you to be methodical and observant, and I am sure you were an excellent ward clerk, but on the morrow you may be a doctor, so will you kindly discard the irrelevant observations, bring out your main points and display a little inductive reasoning by putting two and two together." Often he then says: "I should like to have an x-ray examination, a blood count, a test meal, a bacteriologic investigation of the urine," and so on. That man is likely to remain a ward clerk throughout his life, the medical profession is full of such. Is it altogether his fault, or is it the fault of his teachers and examiners?

Every one knows that the examination system is defective. I wish that the whole stultifying outfit could be abolished. You will reply that examiners require a definite answer to each of their questions and that they expect each of the problems presented to you to be solved in a nutshell. They require nothing of the kind, there is nothing definite in medicine, which is not an exact science, diagnosis is inevitably a matter of probabilities and therein lies its fasci-

nation. It is true that a few examiners while masquerading as physicians are blessed or cursed with the mentality of schoolmasters, but the majority are well aware that our profession is called on to deal with the intangible complexities of human nature, they are out to discover how much you know rather than the gaps in your knowledge, above all they require evidence of a well trained mind and your ability to deal with a clinical situation.

### ESSENTIALS IN DIAGNOSIS

There are two great essentials in diagnosis—a sense of relative values and that inductive reasoning which threatens to become a lost art in medicine. We must never overlook the immeasurable importance of these essentials, otherwise we shall always miss the wood for the trees. Here is a great danger for which I am inclined to blame the system of piecemeal investigation imported from America and Germany under the blessed name of clinical research. I am not belittling genuine research. I am all for genuine thoroughness and accuracy of observation. But it should be obvious that many of those endless series of irrelevant and uninspired "clinical investigations" with which our laboratories and special departments are inundated indicate (a) that some one contemplates writing a paper or (b) that some one is hiding his lack of wits or courage under a cloak of pseudoscientific enterprise. I venture the opinion that 80 per cent of the work performed by the clinical laboratories and x-ray departments of today is more or less unnecessary, although it is conducted under the noble guise of team work. There is a worse feature than this: thousands of patients are continually becoming hospitalized. The saddest feature is that a new generation of medical men is being embarked with but the scantiest notion of diagnostic values. I cannot see the point in hospital practice where added burdens are imposed on all concerned without financial reward. Nor do I understand why our investigators fail to go the whole hog while they are at it, why not have every available body fluid examined with reference to every chemical constituent and micro-organism known to science? Why stop at hydrochloric acid and the Wassermann reaction?

Closely associated is the departmental danger. Patients today are fortunate if they happen to make first contact with the profession by consulting a really good clinician. Otherwise they are likely to gravitate toward a department or an enthusiastic specialist. Take for example the case of a neurasthenic female who is below par and likely to remain so unless some philanthropist endows her with £500 per annum free of income tax. She displays a multiplicity of symptoms and it is a matter of luck as to which department she reaches. If she goes to one, she will have a test meal, x-ray examinations and so on, if she goes to another she will have a cystoscopy, yet another will oblige her with a rectal examination and possibly sigmoidoscopy, or they might remove her appendix. If she comes to us, we are supposed to conduct a vaginal examination. I might tell her that she is tired out or advise her to take the air in the park. But she would think me a fool and I should be exposed to the criticism from medical onlookers of being frivolous and lacking in professional conscience. So one merely returns a negative diagnosis and makes an attempt to steer her clear of other departments. The onus is not on us but on the man who sent her to us, but we try to be human. You may gather that I assume the majority of patients nowadays to be psychoneurotic. That is true, they are, but beware of the underlying danger. Every neurotic must die of something some day, and it is at least debatable whether it is better to let one neurotic die undiagnosed than to diagnose and treat nonexistent organic conditions in the ninety-and-nine. The real difficulty arises when psychoneuroses and organic pathologic lesions coincide in the same individual, that demands clinical acumen.

#### IMPRESSIVE WORDS

On many occasions I have held forth on the danger of seeking an all embracing label to describe a complex clinical condition. For example, is it conceivable that any well informed individual would attempt to summarize in a word or sentence the infinitely complicated processes involved in normal menstruation, much less the abnormal? And yet we are assailed on every hand by a public which demands a simple nominal solution. Doctors and dressers say "Well, what is the answer?" Patients and their relations say "We insist on getting to the bottom of this, what is the cause?" Poor ignorant souls, they are very trying and often infuriating. What can their conception of a *primum mobile* be? I wish we could give them the answer they require—it seems far more important to them than treatment, but most of us have a streak of honesty which prevents our inventing an impressive word to meet the occasion. Do it if you wish, tell them that

they have the colitis, the acid, the anemia or the glands, but that way lies quackery. Leave it to the venders of "patent medicines" and to the appendicetomists, if we would save our professional souls we must keep the party clean. Some one must hold the fort of truth in a world that is hysterical, confused and seeking miracles. It is even better to say "I do not know."

#### THE SUPREME ARTIST

The supreme artist in clinical diagnosis regards the patient, not the disease, as an entity. He takes into account every relevant feature, general and local, physical, psychologic and environmental. He assesses the relative importance of these features and forms a mental picture or conception of the whole. This picture he can convey to others without any long rigmarole provided those others are intelligent clinicians rather than superannuated ward clerks. The great essentials are a sense of proportion, born of extensive experience or imagination, and a capacity to reason by induction. Generally a surgeon tends to be too quick in forming a judgment, since he is so frequently called on to be quick in action. A physician tends to be too slow and he often fails to reach a conclusion of any practical value. It has been part of my theme that conclusions are not always attainable in medicine.

In obtaining a clinical history, bear in mind that few patients are capable of making a plain statement of fact. Their observations are colored by their own interpretations, by what the other doctor said or by fortuitously coincident phenomena.

We have been taught to avoid any diagnosis that involves a "double pathology." This is bad and dangerous teaching. Do not be afraid to diagnose two, three or even twenty more or less independent pathologic conditions in one and the same individual.

Beware of the fixed idea in patients and colleagues alike. It is regrettable that some of the most eminent members of our profession are obsessed with fixed ideas which nothing will persuade them to discard. This implies that at some period of their career they have crammed up and pigeonholed some comprehensive subject, possibly with a thesis in view. These men are often excellent teachers—at any rate they are dogmatic but they have sacrificed one of our greatest diagnostic gifts, the open mind.

It is always helpful to see the patient's husband or wife. You may learn more from a brief acquaintance with him or her than you will from a whole series of investigations.

Diagnosis by elimination is a feeble mental process which is all too prevalent. I suppose we must blame in part that oft repeated question "Give the differential diagnosis." If a

woman has a pain in the right lower quadrant, and you have satisfied yourself that she is not suffering from appendicitis do not send her along to us labeled "salpingitis" when there is not a single feature in her history or physical condition to suggest that diagnosis. Call it a pain in the right side of unknown origin, salpingitis is a definite entity.

Diagnosis is largely a matter of probabilities. Keep your eyes open to every possibility but never despise the obvious.

#### IMPORTANCE OF CONCENTRATION

Finally, let me impress on you the supreme importance of concentration. We live in the midst of distractions of every kind, it is difficult to keep our heads clear. But when a patient consults you, that patient for the time being is entitled to the full use of every ounce of your gray matter whether you spend two minutes or two hours in making your diagnosis. Never mind the woman you delivered last night, the operations you performed yesterday or those you are going to perform tomorrow, never mind the patient you have just seen, never mind the telephone. In the practice of medicine you can do only one job at a time whether you are quick or slow. If the rest of the world seems to be pestering you with all its troubles, turn to it a blind eye and a deaf ear whenever you are applying your faculties to the art of diagnosis.

#### THE TRAINING OF SPECIALISTS IN OBSTETRICS AND GYNECOLOGY

*Abridgment of address by Dr. N. Sprout Heaney, Chicago, published in the American Journal of Obstetrics and Gynecology, November 1938.*

It may not be amiss for the president of the American Gynecological Society to express a few thoughts relative to the training of specialists in obstetrics and gynecology. From the large number of applications for residencies received everywhere it is apparent that great care must be taken if sufficient suitable positions are to be supplied. There are many hospitals which accept interns for their fifth year's work where the practice of the hospital is so specialized or the rotation of the internship is so restricted that the intern does not get a good general training. Six months' service in internal medicine and six months in general surgery are commonly accepted as a substitute for the required internship. This would not seem comprehensive enough for entering general practice in which so much of the practitioner's work has to do with obstetrics and the care of sick children, nor is it a sufficiently broad experience to use as the base on which to build a training in some specialty. Furthermore, when the service in internal medicine may be

limited to metabolic diseases and the surgical experience may be largely limited to abdominal work, the training the intern receives lacks much of what should be expected. It may be possible for an intern to get a better training on a rotating service in a less famous hospital in which the work is more general and less highly specialized. When the work offered an intern by any hospital is not general enough, the medical colleges should remove such an institution from their lists of hospitals approved for internship.

Special hospitals and teaching hospitals become available at once for the training of specialists by replacement of the fifth year internships with special internships and residencies. We are looking for methods of measurement to determine goals of achievement and are confronted by the fact that our measuring stick must be flexible instead of rigid. There is no inflexible standard for measuring professional ability. Self-made men may excel the products of long training, yet training is generally requisite for competence and a minimum standard seems advisable. The length of residency in an institution required for certification would vary with the opportunities offered but should not be longer than three years. To remain too long in one institution is a real danger for a young man. It is too likely to fix his ideas and limit his development. Too long a period of training in one institution produces the man anxious to tell of his institution's methods of treatment instead of the eager seeker after new methods for his own improvement. This residency period should be broad in its experience and active to the extreme. Contemplation does not develop diagnostic acumen, nor philosophic discussion surgical technique. Clinical material should be abundant and responsibility for its management developed. Thorough training in the anatomy and pathology of the specialty is of prime importance. Though a man expects to be an obstetrician he should during these years have enough training in gynecology so that he may be a safe operator in obstetrics when the occasion arises. Now that services in obstetrics and gynecology are commonly combined he should prepare himself for that possible contingency in his future and have a good basic training in gynecology. So should the aspirant in gynecology have, during these hospital years, a good training in obstetrics. The stamp of the obstetrician is seen in the character of every gynecologist's work who has been trained in both branches.

#### SEEK ANOTHER CONNECTION

After three years, sometimes sooner, he should leave the hospital of his special training and seek some other connection. Nothing is so illuminating as a change of chiefs. The next year he might well spend in travel and in taking

special courses to make up the deficiencies in his training. In one center he would find much to stimulate him in investigation, in another he would find an entirely new attitude toward clinical problems which had been satisfactorily settled as far as his previous training had led him to believe. An impressive teacher may so imbue a student with his beliefs and methods that the student feels no urge to seek further fields for truth, and inbreeding results. There seems something innate in the active surgical teacher which gives the impression that all truth rests in him. It might not be advisable to disabuse the minds of patients, nurses and secretaries regarding the fallacy of this created opinion, but we really owe it to our own assistants to rob them of this delusion, so that they in turn may not be bound by our own limitations. Many of us in charge of large clinics have discarded every operative procedure which we once employed and have established new technic, based on ideas picked up here and there while visiting elsewhere.

#### RESEARCH WORK

Or this fourth year might be spent in a research laboratory. There is a move on foot to require research work of every candidate for specialization. This is laudable if practicable. Progress in medicine can be expected only through investigation. The man with a research type of mind can best evaluate the clinical application of new discoveries, but shall we require this as a necessary qualification for licensure? What constitutes research work in gynecology and obstetrics? In our specialty much acclaim is given the one who works in physiology, chemistry or physics. Formerly reputations were established by research into the morphology of tissues. Not much credit is given to the student of histology today as being engaged in research work, yet the studies of Sampson on endometriosis has had far more effect on the practice of gynecology than any other single bit of research done during the same period in obstetrics and gynecology, whether test tube and guinea pig were used or not. So, before research is required, research must be defined. A great deal of self deception exists as to the real value of the research work we engage in. In his fourth year a young specialist should be full of problems demanding solution if he has a research mind, and a year under a recognized investigator will teach him exact methods. Research work must not be a fetish and should be an addition to adequate clinical and technical training. It should not be considered a substitute.

After the third hospital year, the aspirant may be taken into a specialist's office as an assistant for further training. This is not only

helpful to the chief but can be made of the greatest value in the training of younger men. In the hospital the resident has seen chiefly the seriously sick, or at least those requiring hospitalization. In an office or dispensary practice he sees, in addition, the beginnings of disease and finds that many applicants for medical relief need only the assurance that nothing ails them to obtain that relief.

#### ACCEPTING ASSISTANTS IN OFFICE

Years ago I became aware that if I were to train teachers for my staff at the college and hospital I would have to do it through accepting assistants in my office, for the teaching and clinical beds were too few to train the men in a reasonable time. I remodeled my office so that a large number of patients could be attended. Fixed fees were abandoned and all who wished attention were made welcome. As largely as possible the active care of patients was turned over to assistants and my attention was given to the supervision of their work and the treatment of the most exacting or complicated cases. Obstetric and gynecologic cases were handled alike and the fees of the poor and of persons with limited means were largely a matter of their own decision. The rich came along with the poor, were charged abundantly, and were happy in most instances to pay the fees exacted, because they had before them the visible reasons for variations in fees. Assistants were taken on for a period of three years. In order that the assistants' activities could be controlled and their time best occupied for their own advancement, flat salaries were paid for the disposition of all their time and efforts, and the salaries were increased for each year of service. The salaries were sufficiently ample so that at the end of three years the assistant could pay for a year's study abroad. When this calculation failed I lent them enough money to make up the deficiency. After returning from his foreign training the assistant goes into private practice on his own responsibility. He is allowed to notify such of my clientele as were earlier turned over to him for his attention that he is in practice for himself and he is given a position on the staff of the hospital and on the teaching staff of the medical college. Each of these graduates from my office is assured of a private practice in his specialty out of my own clientele, but this pruning has never injured the parent practice. In this way one may make up the deficiencies of insufficient institutional positions both to the progress of obstetrics and gynecology and to one's own satisfaction.

Surgery is an art, dexterity and proficiency in it come only through much training and hard application, and for the acquisition of this art there can be no substitute for a large experience.

We deal in human lives. Quick judgment may be based on temperament but its chief support is experience. Operative dexterity is an asset best appreciated when dealing with the poor operative risk. Many people die from operations who might live were the operator a little more skilful, a little more experienced. Why do we try to substitute something else for this indispensable attainment? In the last analysis examinations for licensure have not as yet been devised which will indicate a candidate's real ability.

### STUDENT WILLIAM BEAUMONT

Dr. William Beaumont, the pioneer American physiologist, accomplished under discouraging circumstances some of the most remarkable medical research of all time.<sup>1</sup> Born on a farm in Connecticut in 1785, Beaumont grew up in a puritanical atmosphere. With no particular destination in mind, he left home when 21 and drove northward in a sleigh, arriving in the spring at the village of Champlain, New York, where he taught school for three years and tended store. Here Beaumont manifested great interest in national affairs. He wrote his father that he planned to enter the army in case of war, which seemed near. On his way to Champlain he had met Dr. John Pomeroy of Burlington, a practitioner who later taught anatomy in the University of Vermont, and from him probably received the urge to study medicine. Having saved enough money to see him through the two years of medical apprenticeship, Beaumont crossed the lake to St. Albans and became an apprentice to Dr. Benjamin Chandler, an excellent teacher. At this stage in his career the qualities which were to make him famous were already evident. Every case history was an example of precision. His attitude during the apprenticeship is disclosed in a letter to his parents: "My situation affords a pleasant life, though it requires my utmost diligence and perseverance in the pursuit of a medical profession in which I hope to exhibit specimens of proficiency in an art which, in this enlightened age of reason and under the modern improvements of chemistry and physiology, bids fair to rise with healing on her wings. I am considerably in the habit of riding with my preceptor and have charge of many of his patients during his calls elsewhere, which are numerous and at a distance. He has just returned from a distant patient and is now gone twenty or thirty miles to perform an amputation."

Beaumont was licensed to practice in June 1812. Still intensely interested in his country's affairs, he went to Plattsburgh to enter the army and promptly became most deeply engaged in

the War of 1812. In his well kept diaries he wrote of the battle of Fort George. The British "devised the inhuman project of blowing up their Magazine (containing 300 Bbls powder), the explosion of which, shocking to mention, had almost totally destroyed our Army. Above 300 were wounded, and about sixty killed dead on the spot by stones of all dimensions falling like a shower of hail in the midst of our ranks."

A most distressing scene ensues in the Hospital—nothing but the Groans of the wounded and agonies of the Dying are to be heard. The Surgeons wading in blood, cutting off arms, legs and trepanning heads to rescue their fellow creatures from untimely deaths."

Beaumont resigned in 1815 and entered private practice at Plattsburgh. The minutes of the Clinton County Medical Society, which he joined in 1819, show that Beaumont was an active member. Although busy in private practice, Beaumont reentered the army in 1820. He was ordered to report at Fort Mackinac, Michigan. The journey from Plattsburgh through the canals, over the lakes and by stage, he vividly describes in a diary. Arriving at Mackinac, he took charge of the small army hospital.

### ALEXIS ST. MARTIN WOUNDED

John Jacob Astor had established the American Fur Company and Mackinac had become a center for collecting furs. The only physician within 300 miles was William Beaumont. Three thousand Indians and French-Canadian voyageurs brought furs to Mackinac in the summer, living in tents along the beach. On June 6, 1822, a shot gun was accidentally discharged in a store of the American Fur Company. Alexis St. Martin, standing less than three feet away, received the blast in his abdomen and chest, and an opening was made that would have admitted a fist. Beaumont took the young voyageur, helpless and destitute, into his home in the fort, where he nursed and sustained him for nearly two years. The record of St. Martin's case covers many pages of a large ledger, in which Beaumont made daily notations. On December 13, for example, he wrote: "To facilitate the closing of the puncture of the stomach, and remove the impediments to the granulations, which the constant pressure of compresses necessary to retain the food in the stomach from day to day cause, I made fast a piece of lint to a ligature, just large enough to pass through the orifice into the stomach, and then with the end of the probe pushed it on the inside, and suspended by the ligature, drew it up against the inside of the orifice, so as to stop the food from flowing out upon the inner side, and by this means suffering the granulations from the edges of the wound to contract nearer each other around the small ligature." When the wound

<sup>1</sup> Myer, Jesse S. Life and Letters of Dr. William Beaumont, St. Louis, C. V. Mosby Company, 1912. Dr. William Beaumont, Bull. Soc. M. Hist. Chicago 1, 150 (March) 1913.

healed there was still an opening into St Martin's stomach from which gastric juice could be collected and the process of digestion observed. Three years after the accident the idea occurred to Beaumont to undertake a series of experiments. These were scarcely started when Beaumont was ordered to Fort Niagara, however, he obtained leave of absence to take St Martin on a visit to scientists in the East. On this journey St Martin skipped out to Canada and Beaumont could get no trace of him. Four years after St Martin's disappearance the American Fur Company found him and brought him and his family to Beaumont, who then was stationed at Prairie du Chien. St Martin was in good health. The aperture into his stomach was still open and the experiments were continued. In 1831 a leave of absence was granted to take St Martin abroad to other scientists, but the Black Hawk Indian War started and Beaumont had to remain with the troops. When the war ended he took St Martin to Washington, where he began a third series of experiments and reviewed the literature on digestion. With bottles of gastric juice Beaumont visited Prof Benjamin Silliman of Yale University and Prof Robley Dunglison of the University of Virginia. Silliman suggested sending a specimen to Bertzelius in Sweden as the man to make the chemical analysis. A bottle of gastric juice was given to the Swedish consul in 1833, with a letter of introduction from Silliman. Beaumont was eager to learn from any source about that "great solvent in the gastric juice." The most disappointing of all his replies was from Bertzelius.

#### SCIENTIFIC SOCIETIES INTERESTED

With the fourth series of experiments completed, St Martin again went to Canada with the understanding that he would return and go with Beaumont to St Louis, to which city he had been ordered. Scientific societies now desired to study St Martin's case. Among those interested were the American Physiological Society, the British Medical Association and Claude Bernard in Paris. Sixty-five letters passed between St Martin and those endeavoring to bring him back. Beaumont finally sent his son to Canada, but St Martin refused to return. St Martin lived until 83 years of age. Although William Osler tried to obtain permission for a necropsy, offering the family a fair price for the stomach that it might be placed in the Army Medical Museum in Washington, the family resisted all requests. Beaumont's four series of experiments on St Martin numbered 238 in all, from which work he made fifty-one deductions. Many of his deductions are accepted today.

Beaumont's second resignation from the Army was accepted by the President effective Dec 31, 1839. He remained in St Louis in the practice of medicine until his death, April 25, 1853. To

his grave in Bellefontaine Cemetery the St Louis Medical Society makes an annual Pilgrimage on Beaumont's birthday.

#### A HARVARD CLASS AFTER TWENTY YEARS

The members of a class who were seniors at Harvard Medical School twenty-two years ago were asked to state what type of medical practice they had been most attracted to when they entered medical school and what they planned to do now. The record of these replies was recently found by Dr William H Barrow, who reviews them in the *Harvard Medical Alumni Bulletin* of October 1938. Sixty-two of the class of seventy-five are included in this study. The country went to war when most of the members of the class were serving their internships, and yet about 18 per cent of them have achieved the goals they set up for themselves on entering school. Another 3 per cent, although having different preferences in their first and fourth years, are now engaged in a specialty originally chosen. Another 21 per cent changed their preferences during their medical course but are now in the kind of practice chosen in the fourth year. Thus a total of 42 per cent of the sixty-two members of the class of 1916 have kept to the courses originally charted, in spite of the World War and the vicissitudes of practice. On the other hand, 27 per cent who throughout the school period pointed toward a chosen specialty are now in a different type of practice. The largest group, 31 per cent, comprises those whose first year choice, fourth year choice and present practice are all different.

While 27 per cent aspired to be surgeons in their senior year, only 5 per cent are now engaged exclusively in surgery. Eighteen per cent were attracted by internal medicine before graduation, but only 10 per cent now limit their practice to internal medicine alone. Gynecology and obstetrics fell from 11 to 6 per cent. Only 15 per cent of the class on graduation chose general practice, but those ranks have increased now to 30 per cent. The percentages of men engaged in other specialties than those mentioned are 8 per cent in orthopedics, 5 per cent each in public health, otolaryngology and neuropsychiatry, and 3 per cent each in ophthalmology, urology and medical administration. Physiology and pathology, radiology, physical therapy, anesthesia and the United States Army Medical Corps each claim one man from the class. The type of internship chosen by this class followed closely the intentions of the graduates at that time. About 37 per cent took straight surgical, 31 per cent straight medical and 16 per cent rotating internships.

An interesting fact brought out by this study was that only three of the sixty-two men have

died, a mortality rate far below the expected mortality. Furthermore, the professional "mortality" is 0, as all the living members are still engaged in the practice of medicine or in allied science. Thus medicine seems to have an appeal that holds "till death do us part" or, as Dr Barrow suggests, perhaps the training has so fashioned us that there is no avenue of escape.

### THE CONSISTENCY OF UNIVERSITY EXAMINATIONS

The reliability of examinations as a guide to the ability of the candidate and his fitness for further study is a controversial subject. An investigation was made by Dr W G Millar<sup>1</sup> into the correlation existing in grades recorded in certain medical subjects at the University of Edinburgh. The third year teaching and examining at this university are done differently than in most medical schools. In the school year 1928-1929 an important change was introduced and since then the teaching in pathology, bacteriology, pharmacology, therapeutics, medicine and surgery has been coordinated so that the student is taught all aspects of a particular disease at the same time. If the subject being taught in medicine is valvular heart disease, for example, the subject taught in pathology will be endocarditis, in bacteriology, streptococci and the bacteriology of acute rheumatism, and in pharmacology and therapeutics, the actions and uses of the digitalis group of drugs.

With this coordinated teaching, the examinations are also coordinated, being held in spring and summer. In each case the departments concerned are grouped together and share questions. A question may be asked on the pathology of pyelonephritis, the surgical treatment of renal calculus and the bacteriology of urinary infections, while medicine, and pharmacology and therapeutics might share a question on heart disease. Each part of the question is written in a separate book and marked by the department concerned. Before each examination the heads of the six departments and the lecturer meet to map out the questions, and they meet again after each examination to consider the results. The grades made by each candidate in each subject are set out on a schedule and the candidate's claim to a certificate, after having done the work of the class which admits him to the professional examination, is considered jointly by the six examiners. The borderline cases especially are fully considered. The general impression of all who have had to do with the joint examination is that a candidate's "form" from one subject to another is remarkably constant.

To confirm the impression of uniformity of performance, correlation coefficients were calculated between each of the six subjects for each year of a six year period. No repeaters were included in the study, and only the marks of those who attended the whole of each examination were taken.

#### THIRD AVERAGE MARK MADE

The second part of the analysis was an attempt to assess the prognostic value of the combined examination and to compare it with that of the preceding and succeeding professional examinations. The figures correlated consist in the average mark made in the respective examination as a whole. In the first professional examination were averaged the written and oral or practical in botany, physics, chemistry and zoology, and in the second likewise in physiology and anatomy, in the combined examination, the average of written papers in pathology, bacteriology, pharmacology, therapeutics, medicine and surgery, in the third professional examination, written and oral or practical in pathology and bacteriology and in pharmacology and therapeutics, in the final written and oral, forensic medicine and public health, midwifery and gynecology, medicine and surgery, clinical medicine and clinical surgery.

A tabulation shows the values of the correlation coefficient between the six subjects of the combined third year examination for the six years. The high values of the correlations coefficient obtained indicate that the performance of the candidate, even though judged in six different subjects and independently by three or four different examiners in each subject, remains very constant. Correlations were also calculated between the final and other professional examinations and the combined examination for a large group of students. These also showed a very high degree of correspondence. The results of the analysis of the data on the six subjects for the six years indicate that the examinations considered form a reliable guide to the students' academic capabilities.

### TO THOSE UNDERTAKING THE PRECLINICAL SCIENCES

By Dr P M F Bishop Slightly abridged from *Guy's Hospital Gazette*, Oct 22, 1938

The first three years in the life of the medical student are supposed to be the dullest. This is because the subjects studied in the preclinical period are considered by many to be purely academic and to have little bearing on the practical training of surgery, medicine or general practice.

Banish this idea completely from your mind when you enter the medical school. It is true

<sup>1</sup> Millar W Gilbert Consistency of University Examinations, Brit M J 2 1209 (Dec 12) 1936

that you will have to work to a syllabus and that the knowledge you acquire will be determined to a large extent by the requirements of those examinations which must be successfully negotiated before you can enter the wards, where at last you will be dealing with living and dying patients. But there is a reason for everything you will learn in your preclinical studies, and that reason is based fundamentally on the experiences of clinical medicine. The first action of many students when they pass the examinations in anatomy and physiology is to set fire to their notes and to try to get a decent secondhand price for their textbooks. Then they feel they can start afresh on a new life, the life of the wards. But though the medical school is separated from the medical and surgical wards by a spacious park, they are much more intimately united as far as their activities are concerned.

For example, the three subjects organic chemistry, chemical physiology and clinical chemistry, you will find, are so closely linked together that it has been found desirable for the chemistry department and the chemical physiology laboratory to work largely in conjunction with each other, while the methods taught in the course of chemical physiology are those which are used subsequently in the clinical chemistry which is practiced in the wards.

The preclinical sciences are designed as a careful preparation for the subsequent clinical work, and if this is fully realized a new interest will be awakened in biology, physics, chemistry, anatomy, physiology and pharmacology.

#### RELATIVE FREEDOM

Most of you will have come to Guy's straight from school, and when you arrive you will be impressed with the relative freedom with which you are endowed. A record of attendances at lectures and practical classes is kept, mainly for the purpose of qualifying you for the examinations. You must realize, however, that these classes are designed to assist you in your work and not to compel you to work. Your life is in your own hands now. If you wish to take an intelligent interest in the manifold activities of the medical school and of the life of the hospital, you will be amply repaid. If you abuse the freedom which is given you by escaping from these activities, no one will miss you and no one will care very much. Medicine is a hard training for those who have no inherent interest in it, and the time to develop and cultivate that interest is as soon as you enter the medical school.

Do not become onesided. Remember that as a doctor you will come in contact with all kinds and classes of men and women, and you will be expected to take an intelligent part in conver-

sation and to express a reasonable opinion on subjects not directly concerned with medicine. There is no one more boring and depressing than a doctor who has no outside interests, unless it is a group of doctors who are incapable of talking anything but "shop" to one another.

Finally, pay particular attention to taking regular exercise. This not only brings you in contact with your fellow students but is essential from the point of view of your health. The borough is not the most salubrious place to live or work in, and hospital life is strenuous. Try as far as possible to develop an immunity to disease while you are still in the medical school, by keeping fit and in training.

#### THE FINANCING OF UNIVERSITY EDUCATION

Returns from universities and colleges in Great Britain which receive treasury grants, reported by the University Grants Committee, show that there were nearly 50,000 full time and 13,000 part time students engaged in courses of instruction in the academic year 1936-1937. Some decrease in the number of entries has occurred since 1933-1934, while in the nine previous years there was an increase in the total number of students each year. The *Lancet*<sup>1</sup> points out that the present decrease in the number of full time students falls in the arts and pure science groups. The medical group, with 13,263 full time students, represented more than a quarter of the total and was the second largest group of all. Of the full time advanced students, that is, those taking a higher degree or engaged in research, only 6 per cent were in medicine, but of part time advanced students more than 25 per cent of the total were taking medical subjects. Of all subjects, chemistry attracts the largest number of male advanced students, followed by surgery, history, physics, medicine, law and economics. With women, the order of popularity for the higher degrees is research, history, education, English, psychology, botany and French.

The total income of the institutions concerned is nearly six and a half million pounds, 36 per cent of which was supplied by parliamentary grants, 85 per cent by grants from local authorities, 31 per cent by fees for tuition, examination and the like, 14.8 per cent by endowments and 2.4 per cent by donations and subscriptions. Of the fifty-nine institutions to which this report relates, ten balanced their accounts and thirty showed a surplus of income over expenditure, and of those which showed a deficit only nine exceeded £1,000.

<sup>1</sup> The Financing of University Education *Lancet* 1 1105 (June 18) 1938

## Medical College News

*Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items to be considered for publication in the Student Section*

### Examination for the Army Medical Corps

The War Department has announced an examination, March 20-24, for the purpose of qualifying candidates for appointment as first lieutenants in the medical corps, regular army, to fill vacancies occurring during the next calendar year. The examination is open to all male graduates of acceptable medical schools who have completed one year's internship in an approved hospital or who will complete such an internship June 30 and who will not be over 32 years of age at the time it will be possible to tender a commission. Those doctors who do not complete their internships until June 30 will not be eligible for appointment until July 1. The examination will be conducted by boards of medical officers convened throughout the United States and will consist of a physical examination, a written examination in professional subjects and a determination of the candidates' adaptability for military service. Full information and application blanks will be furnished on request addressed to the Adjutant General, War Department, Washington, D. C. Applications will not be considered after March 4.

### Examinations for Internships in Naval Hospitals

An examination is held in November each year for senior medical students of class A medical schools who desire to obtain an internship in one of the United States naval hospitals. Senior medical students who qualify for appointment to an internship will be appointed acting assistant surgeons with rank of Lieutenant (junior grade) for temporary service during the intern year. On satisfactory completion of the internship, the intern will be allowed to appear for competitive examination for appointment as assistant surgeon with the rank of Lieutenant (junior grade) in the medical corps of the navy. Should the intern desire to return to the practice of medicine in civil life, his appointment as an acting assistant surgeon will be terminated and he will be honorably discharged from the naval service. To be commissioned in the medical corps of the navy the candidate must be a citizen of the United States between 21 and 32 years of age and he must pass both professional and physical examinations. On accepting an appointment as acting assistant surgeon for internship, the officer will receive a compensation of \$2,699 a year if he has no dependents, and \$3,158 a year if he has dependents. Successful candidates for appointment as interns will be appointed in July and will be assigned for internship to a naval hospital either in Boston, New York, Philadelphia, Washington, D. C., Norfolk, Va., San Diego, Calif., or Mare Island, Calif. The period of internship is one year, is rotating and consists of about five months medical, five months surgical and two months laboratory duties. For additional information address the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

### Internships in the Marine Hospitals

The U. S. Public Health Service desires to receive applications for appointments as second year interns in the marine hospitals operated by the service. Applicants must not be over 30 years old, must have graduated from accredited medical schools and must have completed one year's internship at approved hospitals by next June. Second year internships at marine hospitals are similar to residencies in general hospitals.

Appointees will receive a gross pay of \$1,800 a year, from which a deduction of \$690 a year will be made if quarters, subsistence and laundry are furnished. Those assigned to the federal penal and correctional institutions will receive \$1,620 a year, from which \$240 will be deducted if quarters, subsistence and laundry are furnished. It is especially desired to receive applications from candidates who are interested in the service as a career, and appointments will be made with the understanding that opportunity will be afforded to take the next examination for appointment as assistant surgeon. The rank of assistant surgeon corresponds in pay and allowances to that of first lieutenant in the U. S. Army. Those who wish to make application should communicate at once with the Surgeon General, U. S. Public Health Service, Washington, D. C., stating definitely that they are interested in a second year internship and giving the earliest date of their availability.

### Dr. James B. Herrick Honored

At the 194th convocation of the University of Chicago the honorary doctorate of science was conferred on Dr. James B. Herrick, who for thirty-seven years was a member of the faculty of Rush Medical College. Dr. Herrick is internationally known for his work on coronary thrombosis. Born in Oak Park, Ill., in 1861, Dr. Herrick was educated at the University of Michigan and Rush Medical College, receiving his degree from the latter institution in 1888. He was a founder and the first president of the Chicago Society of Internal Medicine. Dr. Herrick has been president of the Institute of Medicine of Chicago, of the American Heart Association, of the Association of American Physicians and of the Congress of American Physicians and Surgeons. In 1930 he received the Kober Medal of the Association of American Physicians for research in scientific medicine. The University of Michigan conferred the honorary degree of doctor of laws on him in 1937.

### Annual Dinner and Students Clinic Day at Wayne University

The annual dinner of the faculty, students and alumni of Wayne University College of Medicine, Detroit, December 15, at the Detroit-Leland Hotel, was attended by more than 400 and was the climax of a day of clinics and discussions at the college, in which the students organized and carried through four sections of papers and discussions. Members of the faculty had no part in the preparation of papers and clinics but selected from all six that were considered the most excellent, and from these they decided on two for first and second prizes. The first prize was presented by Dr. Raymond B. Allen, dean of the college, to Dr. Kenneth Campbell, Toronto, for his paper on "Alterations in Gastrointestinal Motility, Following Increased Pressure in the Upper Urinary Tract." The prize was the Dr. Max Ballin memorial award medal and \$20, contributed by Drs. Robert C. Moehlig and Norman M. Allen, to which the college faculty added another \$10. The second prize was won by Charles Merckel for his paper on "Comparison of the Effects of Estrone and Testosterone," which was a faculty cash award of \$15.

The prize for the best clinic conducted by the students during the day was awarded, by vote of the

students, to the clinic on electrocardiography. The prize was the Dr. Walter I. Wilson I Memorial Medal and \$20, contributed by Dr. Walter J. Wilson Jr., to which the college faculty added \$10. The chairman of this clinic was Benjamin Jeffries, who was assisted in the demonstration by William F. Goins, Thaddeus S. Huminski, Melvin Silverman and Marvin Schwartz.

Dr. Arthur E. Hertzler, Holstead, Kansas, gave the after dinner address on "How to Get an Education in Spite of the Faculty." Dr. Hertzler is author of the recent best seller, "The Horse and Buggy Doctor."

#### Scholarship Award at Vanderbilt

An annual scholarship award of \$500 has been established by Dr. Ben Witt Key, New York, to some senior of the Vanderbilt School of Medicine, Nashville, Tenn. The award will be effective on the next graduation in June. The winner of the cash award will be that member of the graduating class who is adjudged the best scholar. A committee of three members of the faculty of the School of Medicine will be appointed yearly by the dean, who may also be a member of the committee. The committee is to be governed in its rating of the candidates on the basis of three qualifications: high scholastic rating for the entire period of enrollment in the school (fifth highest or better in the class), outstanding ability in understanding and employing scientific methods of work, the superior traits of character and personality.

Dr. Key received his degree of B.A. from Vanderbilt University in 1905 and graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1909.

#### National Board Questions in Bacteriology

Following are the questions used by the National Board of Medical Examiners in bacteriology and immunology in part one of the examination held Sept. 12-14, 1938.

Answer any five questions. 1. Describe the characteristics of Bacterium tularensis. How is this infection acquired by man? 2. What are the chief pathogenic organisms of the Rickettsia group? Name two diseases caused by them. 3. Outline the method of testing the bactericidal action of a phenoloid disinfectant. 4. What are the three main types of the tubercle bacillus? How is each type identified? 5. Describe echinococcus disease in man. State how the infection is transmitted. How is the diagnosis made? 6. Define the unit of diphtheria antitoxin. How is the potency of a sample of diphtheria antitoxin determined? 7. Describe a bacterial complement fixation test.

#### Fellowship for Women Physicians

The Women's Medical Association of the City of New York announces that the Mary Putnam Jacoby Fellowship of \$1,000 for one year is available for graduate work in the medical sciences. It is open to any woman graduate of an approved medical school, who must be endorsed by the head of the department in which her previous work has been done. The recipient must give full time to the study, which should preferably be made abroad or, if not resident in the United States, she should study in the United States. Applications for 1939-1940 should be filed with the chairman of the committee on or before April 1 and must be accompanied by statements as to health, educational qualifications, proposed problem for investigation and a photograph of the applicant. A report for publication will be required at the completion of the fellowship. The chairman of the committee is Dr. Annie S. Daniel, New York Infirmary, 321 East Fifteenth Street, New York.

#### Dr. Julius Bauer Comes to Louisiana

The dean of the Louisiana State University Medical Center, New Orleans, Dr. Joseph Rigney D'Aunoy, announced Dec. 8, 1938, the appointment of Dr. Julius Bauer of Vienna as clinical professor of medicine effective in January of this year. Dr. Bauer, a native of Bohemia, graduated in 1910 from the University of Vienna and later was appointed docent and professor of internal medicine. In the meantime he had served as demonstrator and assistant in the Neurologic Institute and in the medical clinics of Professors Strumpell and Neusser. He was also assistant in the university clinic at Innsbruck and in the general polyclinic of Vienna. In 1928 he was put in charge of the medical department, formerly directed by Professor Kaufmann. Dr. Bauer has more than 200 publications to his credit, and his five books have been translated into other languages. In 1928 Dr. Bauer delivered the convocation address at the meeting of the American College of Physicians in New Orleans. In 1932 he delivered the Harvey lecture in New York and he has lectured in many other cities. He is an honorary member of the St. Louis Medical Society.

#### Research on Experimental Neurotic Behavior

A prize of \$1,000, awarded annually by the American Association for the Advancement of Science for a scientific paper presented at the meeting, was given at Richmond, Va., to Norman R. F. Maier, Ph.D., professor of psychology at the University of Michigan, Ann Arbor, for his paper entitled "Experimentally Produced Neurotic Behavior in the Rat."

#### Loyola Students Participate in Symposium

The three honorary medical fraternities of Loyola University School of Medicine, Chicago, sponsored a symposium on peptic ulcer given at Mercy Hospital on the evening of Dec. 13, 1938. Introductory discussions on the pathology, physiology and anatomy of peptic ulcer were given by three senior medical students, Alfred H. Benson, representing Lambda Rho, who outlined the pathology, Louis J. Belniak, representing the Volini Society, who discussed the physiology, and Hobart H. Todd of the Moorhead Surgical Seminar, who reviewed the anatomy of peptic ulcer. Then Dr. Karl A. Meyer and Dr. Maximilian J. Hubeny, both of the Cook County Hospital, discussed the surgical and roentgenologic phases of the subject, and Dr. Fred M. Drennan, clinical professor of medicine of Loyola University, discussed the internist's point of view. Invitations were extended to the faculty, student body and members of the staff of the hospitals affiliated with Loyola. This symposium is the first of a series of three planned for this school year.

#### Scholarships at Michigan

On the recommendation of the Committee on Scholarships of the Executive Faculty of the University of Michigan School of Medicine, Ann Arbor, the annual scholarship awards were recently made. Nicholas Lentini received the Misses Armstrong Scholarship, Joseph Henry Kerzman, Miss Elizabeth J. Kitchen and John W. Warren Jr. were awarded the University Scholarships in Professional Schools, the Agnes C. Weaver Scholarships were granted to Malcolm Block and Warren Campbell Hastings, and Samuel Stearns received the Sally Curry Scholarship. The Walter R. Parker Fellowship in ophthalmology for the current year has been awarded to Dr. William J. Stellwagen, instructor in ophthalmology.

### Staff Members Appointed to Faculty

With the affiliation between New York University College of Medicine and the Queens General Hospital during the past year, more than twenty members of the hospital staff have been appointed to the faculty of the college of medicine. Among the appointments were

Dr. Carl Boettiger, clinical professor of medicine  
 Dr. Frank R. Mazzola, assistant clinical professor of medicine  
 Dr. Harry P. Muncken, clinical professor of obstetrics and gynecology  
 Dr. Walter C. A. Steffen, clinical professor of pediatrics  
 Dr. Henry A. Reisman, assistant clinical professor of pediatrics  
 Dr. Frank N. Dealy, clinical professor of surgery  
 Dr. Frederic G. Meynen, assistant clinical professor of surgery

In addition, Dr. Thomas K. Davis has been appointed clinical professor of neurology and the following have been promoted: Drs. Frank C. Combes, to assistant professor of dermatology and syphilology, Timothy J. Riordan, assistant clinical professor of dermatology and syphilology, and Evan W. Thomas, assistant professor of dermatology and syphilology.

### Entertain Women Interns and Senior Students

The senior medical students and the women interns of Chicago were entertained by the Medical Women's Club, the Council of Medical Women, and Branch two of the National Medical Women's Association at a dinner December 14, following which a program of entertainment was presented. Dr. Carroll C. L. Birch, assistant professor of medicine, University of Illinois College of Medicine, was chairman of the committees in charge.

### St. Louis University School of Medicine

Dr. Henry Pinkerton has been appointed director of the department of pathology at St. Louis University School of Medicine, St. Louis, to enter on his duties at the beginning of the new year. Dr. Pinkerton has been assistant professor of pathology at Harvard University School of Medicine, Boston. William Bruer has been appointed professor of dental pathology at St. Louis University, formerly he was director of the dental clinic at the University of Innsbruck, Germany.

### California Personal

Floyd DeEds, Ph.D., in charge of the pharmacology research unit, food research division, U.S. Department of Agriculture and research associate, department of pharmacology, Stanford University School of Medicine, San Francisco, has been promoted to principal pharmacologist.

### The Judd Lecture at Minnesota

Dr. Dallas B. Phemister of Chicago, professor of surgery at the University of Chicago, will give the sixth E. Starr Judd Lecture at the University of Minnesota, Minneapolis, in the Medical Science Amphitheater on Wednesday, February 1, at 8:15 p.m. The subject of Dr. Phemister's lecture is "Pathogenesis of Gallstones." The late Dr. Edward Starr Judd, an alumnus of the Medical School of the University of Minnesota, established this annual lectureship in surgery a few years before his death.

### Scholarship at Woman's Medical College

The Woman's Medical College of Pennsylvania, Philadelphia, announces that a tuition scholarship of the value of \$400 will become available to a student entering the first year of the medical course in September and will be awarded on the basis of a competitive oral and written examination, to be held

at the college April 1. The competition will be open only to students of superior premedical record who furnish convincing proof of need of this assistance. Candidates will be required to fill out a special form of application for admission to the examination. For further details apply to Assistant to the Dean, Woman's Medical College of Pennsylvania, East Falls, Philadelphia.

### Scholarship Awards at Temple

Four students in the Temple University School of Medicine, Philadelphia, recently received the scholarship merit award of the General Alumni Association. These students were John B. Roxby Jr., Swarthmore, Pa. (freshman), Maurice L. Brown, Philadelphia (sophomore), Norman Learner, Philadelphia (junior), and Henry T. Wycis, Leechburg, Pa. (senior).

### Harvard Awards Melvin Scholarships

The award of James C. Melvin scholarships to the following students at the Harvard Medical School, Boston, was recently announced: Bertrand E. Bennett, Newton, Mass.; Kenneth T. Bird, Watertown, Mass.; Tague C. Chisholm, Boston; Philip G. Creese, Danvers, Mass.; David Dove, South Sudbury, Mass.; Arthur R. Hartwig, Lawrence, Mass.; Lawrence Kilham, Boston; Julian Nieckoski, Deerfield, Mass.; Robert J. Tracy, Concord, Mass.; Paul F. Ware, Clinton, Mass.; and Earle H. Webster, Bridgewater, Mass.

### Pennsylvania State Board Questions

The following list of questions in gynecology and obstetrics was submitted by the Pennsylvania State Board of Medical Education and Licensure at the examination in Harrisburg, January 4.

1. Discuss the etiology, symptomatology and diagnosis for the various forms of vaginitis. Outline treatment of one of these conditions.
2. Discuss the differential diagnosis between early and incomplete abortion and tubal pregnancy.
  1. Give the arguments for and against the treatment of incomplete (partial or marginal) placenta previa by cesarean section.
  4. Describe the various methods of constructing an artificial vagina. Tell something of the advantages and disadvantages of each and describe one of these procedures in detail.
  5. Given a woman, age 66 years, who had a hysterectomy at the age of 30 and who in the past six months has developed a painless but marked distention of the abdomen, describe in detail the differential diagnosis and suggested procedure in treatment.
  6. Give the etiology, symptomatology and pathology of salpingitis. Give your method of treatment.
  7. Discuss the complications of labor which may develop by reason of a funnel (android) pelvis.
  8. Describe the various malpositions of the uterus. Tell the causes of each and describe the treatment for these various malpositions.
  9. In the case of a childless marriage, how would you investigate the male and the female for sterility? What treatment would you institute to try to induce the woman to become pregnant?
  10. How would you diagnose threatening endo uterine asphyxia of the fetus during labor? How would you manage such a case?

### Instruction on Tuberculosis at Tulane

Dr. Julius L. Wilson, associate professor of medicine at Tulane University School of Medicine, New Orleans, is now full time instructor at the school assigned in the field of tuberculosis and other diseases of the chest. State and parish tuberculosis organizations were instrumental in promoting this form of instruction for medical students and Dr. Wilson's services will be available to them for community campaign work. He graduated from Johns Hopkins University School of Medicine, Baltimore, in 1923 and comes to Tulane from the Yale University School of Medicine, New Haven, Conn., where he was assistant clinical professor and in charge of the tuberculosis division of the William Wirt Winchester Hospital.

## THE ETIOLOGY AND PATHOGENESIS OF ALCOHOLIC CIRRHOSIS OF THE LIVER

CHARLES L CONNOR MD  
SAN FRANCISCO

In order to orient the subject of alcoholic cirrhosis and to understand the differences between it and other cirrhoses of the liver, it is necessary first to review briefly from an etiologic and anatomic point of view the types encountered, as nearly as this is possible at the present time. In a classification the terms Laennec's and atrophic cirrhosis must be abandoned. "Laennec's cirrhosis" means exactly nothing when a proper separation of types is attempted. To clinicians it may imply a symptom complex, but this can be imitated by so many conditions, such as syphilis or carcinoma of the liver, that even in that sense the term can be of but little value. "Atrophic cirrhosis" is more informative to the pathologist, as it occurs most commonly after large amounts of liver tissue have been destroyed, but "atrophic" is only a relative term, used differently by different observers and varying in significance with each. Its use tends only to confuse the subject.

Cirrhosis, originally meaning a color, has come to connote diffuse fibrosis of the liver affecting all lobes in about equal degree. Because of condensation of the fibrous tissue with resultant shrinkage and because of more or less regular lobular regeneration or over-regeneration of liver cells, the liver may become nodular or "hobnailed." Some livers may be markedly cirrhotic (fibrotic) without having this surface irregularity. The classification which follows explains some of the differences which may be recognized and is meant only to clarify this paper. It is essentially a modification of that used by Mallory<sup>1</sup> years ago.

1. Toxic cirrhosis is the cirrhosis following necrotizing lesions of the liver, which when severe are called acute or subacute yellow atrophy or hepatitis and when "chronic" are usually recurring attacks of the same condition. In this type there is loss of liver cells, which have been completely broken down, with the soluble

material absorbed and the insoluble phagocytized by small and large leukocytes. Collapse of the stroma follows, and, while fibroblastic proliferation may occur, much of the sclerosis is due to condensation of the pre-existing fibrous tissue and obliterated vascular framework. This produces the smallest and most irregular livers, depending on the degree of destruction and the amount of regenerated liver. Among the causes are phenylcinchoninic acid (cinchophen, atophan), arsenic compounds, severe thyrotoxicosis, so-called acute catarrhal jaundice and acute infectious jaundice (ictero-hemorrhagic leptospirosis, Weil's disease). Frequently the cause of the preceding necrosis is unknown. It occurs in children, women and men, alcoholic or non-alcoholic, indiscriminately.

2. Biliary cirrhosis is a type of portal cirrhosis, as the lesions begin in the portal areas around bile ducts. It is always associated with biliary obstruction, with or without infection. The common causes are therefore common duct stones, carcinoma of the head of the pancreas or the ampulla and a group of miscellaneous conditions such as adhesions around the common or hepatic ducts following infections. The liver is at first large, tense and green. It is nodular even in the early stages because of hepatic swelling and consequent bulging of the surface lobules. The lesion is inflammatory, manifested by accumulations of macrophages, lymphocytes and occasional polymorphonuclear cells, and accompanied by fibroblastic proliferation. While bile is dammed back to the centers of lobules, the irritating effect is produced where bile canaliculi normally join with bile ducts at the periphery. The severity depends on three variable factors: the degree of obstruction (partial or complete), the length of time the obstruction exists and the presence or absence of infection. On these factors also depends the end result, whether the liver returns functionally to normal if the obstruction can be relieved or whether it contracts sufficiently to cause permanent portal obstruction.

3. Pigment cirrhosis is another type of portal cirrhosis. It is most commonly associated with the accumulation of iron-containing pigments in the disease hemochromatosis. Milder degrees have been found with pernicious anemia, particularly after a large number of blood transfusions have been given. A similar condition has been produced by feeding copper to animals, mostly rabbits.<sup>2</sup> A few cases have been reported in workers with copper. The irritating pigments and metals collect around the periphery of lobules and cause a macrophage and fibroblastic proliferation from the periportal connective tissues. The liver is not generally decreased in size and has a relatively smooth surface.

From the Division of Pathology, University of California Medical School.

Read before the Section on Pathology and Physiology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

Material for this paper was collected for ten years from the University of California Hospital, the University of California Service of the San Francisco Hospital (Department of Public Health), the San Francisco coroner's office through the courtesy of Dr. T. B. W. Leland and the cooperation of Dr. Jesse L. Carr; information supplied by the late Dr. A. A. O'Neill, former city prison physician and experiments on the effects of alcohol on animals conducted in collaboration with I. L. Chaikoff (Connor, C. L. and Chaikoff, I. L., *The Development of Cirrhosis in Fatty Livers*, *Arch. Path.* 25: 761 [May] 1938). The paper is a condensation of a report to be published in greater detail later.

<sup>3</sup> Footnote deleted on proof.

4 Fatty cirrhosis is a third type of portal cirrhosis, in which the lesions develop around lobules, joining the portal areas into continuous bands of fibrous tissue. It results from pressure atrophy of cells and hyaline and fatty degeneration of cells at the periphery of lobules followed by fibroblastic proliferation. It is caused most commonly by or is associated with long-continued alcohol poisoning and diabetes mellitus with which there has been a preceding fatty infiltration of the liver. It has been experimentally produced by feeding carbon tetrachloride<sup>4</sup> and phosphorus<sup>5</sup> and in depancreatized dogs<sup>6</sup>. Fatty infiltration and occasionally cirrhosis may occur in cases of hypothyroidism or lesions of the pituitary and midbrain as in cases of progressive lenticular degeneration (Wilson's disease). In all these there has been an alteration in lipid or carbohydrate metabolism or both.

This grouping does not include the scarred liver resulting from adventitious focal necroses, healed abscesses or healed syphilis. The effects of such lesions if any, depend on their position and extent. They are not progressive, are not uniform and usually are not diffuse, and symptoms resulting from them are due to accident of position. The diffuse fibrosis of healed congenital syphilis is a pathologic curiosity. I know of no specific type of cirrhosis associated with so-called Banti's disease.

It can be seen from the foregoing that the lumping of all types of diffuse fibrosis of the liver under the general term "cirrhosis" has no meaning. The often repeated assertion that alcohol cannot cause cirrhosis of the liver because women and children who have never drunk alcohol get cirrhosis seems more than a little absurd. Clinical differentiation on a basis of causation is frequently not easy, but until the attempt is made a rational understanding of the disease is not possible.

There can be little doubt now that alcohol and the habits induced by the consumption of large amounts of alcohol are the most important factors in the production of fatty liver, which passes on in some cases to cirrhosis. A careful review of 130 histories of cases in which cirrhosis or fatty liver or both were found revealed that the factor next in importance to alcohol is the abnormal diet which invariably accompanies severe chronic alcoholism. One can further reduce this to a specific lack of sufficient carbohydrate in the diet.

After the fact is established that chronic severe fatty infiltration of the liver would in time become cirrhosis, the search for etiologic agents narrows down to the condition which will produce the first stage. Fatty infiltration of the liver occurs with a large number of diseases and is incidental to poisoning by such substances as phosphorus, chloroform, carbon tetrachloride and alcohol. The most common spontaneous disease in man with which long-continued severe fatty infiltration is associated is diabetes. The same condition occurs in depancreatized dogs with diabetes, and if such dogs are kept alive long enough a cirrhosis of the liver develops which is indistinguishable from the fatty cirrhosis occurring in man<sup>6</sup>. Thus the occasional cirrhosis which has been noted for many years in diabetes mellitus has been explained. In this disease the fatty infiltration is due to the lack of proper sugar metabolism and the incomplete oxidation of fat. The storage of fat in the liver

is accompanied by a markedly reduced respiratory quotient. Himwich and Fazekas<sup>7</sup> have recently shown that the respiratory quotient of liver tissue itself in experimental diabetes becomes as low as 0.57, far below that found when fat alone is being consumed. With such a lowered carbon dioxide oxygen ratio it must be assumed that very little carbohydrate, if any, is being utilized. Two factors bring about the same physiologic condition in chronic alcoholism. Alcohol itself interferes with carbohydrate metabolism and fat oxidation because of its action as a cell and tissue toxin,<sup>8</sup> and because of starvation or lack of carbohydrate in the diet. Sugar is withheld from the metabolic cycle. According to Higgins<sup>9</sup> the respiratory quotient drops to 0.667 in alcoholic intoxication. In starvation it may be below 0.7. From experiments by Himwich,<sup>7</sup> and Elliott and Baker<sup>10</sup> it is evident that the respiratory quotient of liver tissue itself under such abnormal conditions is always lower than the respiratory quotient of the body as a whole. It seems evident then that when two factors are operating, alcohol and starvation or alcohol plus a protein fat diet, all of which cause a marked lowering of the respiratory quotient, the liver will accumulate unoxidizable fat and that liver cells will be deprived of oxygen and nutrition. The liver becomes an unnatural storehouse of fat and approaches, so far as oxygen carbon dioxide exchange is concerned, the normal fat storage tissues of the body, in which this is very low. There is then a complete depletion of glycogen from the liver, the absence of which renders it more susceptible to all poisons of this nature.

The usual effect of relative anoxia on cells in general pathologic processes seems to be enhanced in the liver. I refer to the type of cell degeneration which accompanies a decrease of oxygen in tissues below the amount necessary for normal function. This results, in whatever organ concerned, in a slow atrophy of cells, frequently manifested also by coagulation and hyaline degeneration of the cytoplasm. When more acute and more severe restriction of oxygen takes place, necrosis of cells, with or without fatty degeneration, occurs. In both cases fibrous tissue develops, partly as a direct result of relative anoxia and partly as a reparative process following death of cells. These processes occur in the liver when the physiologic condition just described is produced by alcoholic poisoning and the consequent restriction or inhibition of carbohydrate metabolism becomes severe (Connor<sup>10a</sup>).

By alcoholic poisoning and severe chronic alcoholism I mean the constant consumption of sufficient alcohol in any form to alter materially the normal carbohydrate fat metabolism or the consumption of large amounts so frequently that normal metabolism may not be reestablished in the intervals. To comprehend this the ordinary drinker must discard his somewhat naive and amateurish conception of what constitutes a "heavy drinker." One is astounded to learn, that a "two bottle man" means a 2 quart bottle man and not two pints a day and that men, and now very frequently women, may consume a gallon or more of sherry wine (from 20 to 22 per cent alcohol) in twenty-four hours, and one

must keep in mind that most alcohol addicts, like morphine addicts become pathologic liars when questioned in routine history taking. They have acquired some degree of tolerance which must mean that their metabolism has become adjusted to the physiologic level at which alcohol burns, just as man may become adjusted to a diet of protein and fat alone with a permanently lowered carbon dioxide oxygen exchange. This tolerance is broken through when the liver becomes filled with fat, and the time comes when very small amounts of alcohol may cause a degree of lasting intoxication. This is so in experimental animals after a time smaller and smaller amounts of alcohol are needed to keep them in a constant state of semicomatose.

From the large number of cases studied composite pictures may be assembled to illustrate three phases of disease of the liver produced by alcohol. The three phases occur at the ages of about 40 to 45, from 50 to 55 and from 50 to 65, respectively, the ages overlapping as would be expected from the nature of the disease. When it is understood that the first acute stage may be reached in from six months to two years, the second in from one to five years and the third in from two to twenty years or more, it can be seen how unreliable age statistics are. The age is usually above 40, because men usually do not begin to drink the quantities of alcohol necessary to produce these changes until after that age.

1 The acute fatty liver of alcoholism develops after the prolonged use of very large amounts of alcohol during which little or no food is taken or the food consists of protein and fat only.<sup>11</sup> It is found in men picked up by the police who die shortly afterward in prison or in city hospitals. It is most common in the coroner's morgues in all large cities. When the patient lives long enough for clinical examination he may show signs of cirrhosis such as jaundice and some ascites but has a large liver. The liver is pale and greasy containing about 60 per cent fat. It may be lobulated because of the severe swelling but is usually smooth. Because of the swelling also there may be intrahepatic obstruction to bile ducts, giving a green coloration, and portal obstruction without fibrosis. Such livers are recognized by all medical examiners as due to alcohol and as being associated generally with poor nutrition. The patients who die in this stage represent the inevitable mortality during the experimental production of cirrhosis in man. The others pass on to the next stage.

2 The fatty liver in which there is early but definite and progressing perilobular fibrosis is the product of alcoholism which is less in degree than that causing the first phase but which is nevertheless severe. In the liver which survives drastic alcohol poisoning and partial starvation diets, a fibrous tissue stroma will develop in the course of time. The liver is large or normal in weight and moderately lobulated or smooth. It is sclerotic, may or may not be bile stained and produces classic early signs and symptoms of cirrhosis. The condition is the common fatty cirrhosis of the liver found in most classifications.

3 The liver in the third phase is likely to be somewhat reduced in size and to have a nodular surface and a thickened capsule. It never becomes as small as the liver of toxic cirrhosis, seldom weighing under 1,300 Gm. Fat may or may not be present. The condition follows the long-continued use of excessive amounts of alcohol by persons who have continued to eat a better

diet, but both as to alcohol and diet the habits have been abnormal. There may have been intermittent severe episodes of drinking lasting long enough to damage the liver permanently. To produce this condition requires much more than could be called a moderate use of alcohol, but it can be understood how by alternating the two primary factors involved, alcohol intake and diet, the process might be accelerated or retarded indefinitely. This phase forms the classic cirrhosis of the portal type and, because fat may be absent, is classified simply as Laennec's cirrhosis, with a helpless gesture of resignation when the question of causation arises. Fat disappears from the liver when the body fat is exhausted, and the liver becomes smaller after prolonged starvation, fat rapidly disappears when the consumption of alcohol is discontinued, and the resumption of a normal diet or the administration of dextrose solution causes a rapid disappearance of fat as the liver fills with glycogen. The presence or absence of fat, then, has little significance in this late stage.

While it may be impossible to assign degrees of importance to all factors involved in the production of alcoholic cirrhosis, the following summary gives an idea of some of the combinations possible. The one constant factor in all of them is the excessive consumption of alcohol. This does not preclude the possibility that other factors contribute to the metabolic condition produced in some cases. It is uncommon, however, to find any such conditions at autopsy.

1 Starvation or partial starvation and the continuous use of large amounts of alcohol. This produces fatty livers from which the patients may die before cirrhosis develops.

2 Diet restricted to protein and fat plus alcohol.

3 Diet containing some but an insufficient amount of carbohydrates and vitamins, plus large amounts of alcohol habitually. This diet may prolong the time of development of cirrhosis by years.

4 A sufficient diet plus alcohol, alternating with periods of severe alcoholism with an insufficient diet, these periods coming so close together that in the interim the liver has not had time to return to normal.

5 Diet adequate in protein, fat, carbohydrate and vitamins, that is, a balanced diet plus alcohol. Whether any one on such a diet will have alcoholic cirrhosis is very doubtful. A person eating three regular, balanced meals a day will probably not become a chronic alcohol addict in the sense that this term is used here, as long as this regularity continues. It has been demonstrated in both man and experimental animals that it is possible to maintain metabolic equilibrium within safe limits even when large amounts of alcohol are taken habitually.

#### ABSTRACT OF DISCUSSION

DR ERNEST M. HALL, Los Angeles. I believe Dr Connor is on the right track. Practitioners have been trying for years to produce cirrhosis of the liver experimentally and have succeeded by the use of copper but not by the use of alcohol. We became convinced recently that the reason for failure is that the animals have received an adequate diet. I have been teaching classes for some three years that the alcoholic type of cirrhosis is probably due to use of alcohol plus an inadequate diet. I am studying a group of cases from the Los Angeles County Hospital selecting sixty-eight on the basis of enlargement of the liver, which usually weighs from 2,000 to 5,000 Gm., and of the fact that microscopically the liver is still active—that is, necrosis is still going on in the hepatic cells and the connective tissue is relatively young and active, as Dr Connor has shown in his photomicrographs. There is considerable fat in a great many of the livers. In about one

11 The peculiar metabolic condition established in alcoholism which demands more alcohol or food as fat and protein which causes a respiratory exchange in tissues approaching that of alcohol needs to be investigated.

third of the cases comparatively little fat is seen. The history of the patients is interesting. Eighty per cent of them were definitely alcoholic. Of the twelve who had no record of alcoholism, eight were severely ill when they came into the hospital. One had lobar pneumonia, one confluent bronchopneumonia, two generalized peritonitis from ruptured appendix, and so on. It is not remarkable that no history of alcoholism was obtained in these eight cases. That leaves four cases in which there is no history of alcoholism or no reason for the omission. Only one person of the sixty-eight stated that he had not used alcohol. I believe with Dr Connor that these large quantities of alcohol affect the liver, especially when the person fails to take an adequate amount of food. Herter and Williams have shown in subjecting dogs to chloroform anesthesia that if they repeat the procedure every day for three or four weeks—not allowing the liver to recover between times—they produce definite cirrhosis of the liver, whereas Whipple and Sperry showed that, after two or three prolonged periods of anesthesia with chloroform necrosis of the centers of the lobules developed and yet cirrhosis of the liver failed to appear.

DR FRANK RAYMOND MINNI, Portland Ore. Dr Connor has opened an old controversial subject, which was made the subject of the International Association of Pathologists meeting several years ago. Their final conclusion was that while they could incriminate alcohol it has never been fully proved to be the logical factor. I recognize two types of cirrhosis with fatty changes in the liver. Dr Connor's sections show those types. In the first the peripheral fibrotic framework becomes more prevalent by virtue of the fat present. That is an atypical form of cirrhosis. Sometimes I hesitate to call it cirrhosis. The second is periportal fibrosis or cirrhosis in which there is also fatty change. It is difficult to separate the "wheat from the chaff" as to whether two independent processes might exist or as to whether cirrhosis might have occurred and then fatty infiltration or fatty manifestation. I agree that certain forms of consumption of alcohol in certain countries seem to bring forth an increased incidence of cirrhosis of the liver. Scotland notoriously having high consumption of alcohol, does not have as great an incidence of cirrhosis as some parts of India, where no alcohol is consumed. Other similar experiences have been brought to light. I with my associates recently had occasion to study twenty-two instances of acute methyl alcohol poisoning, which I have reported in the *Archives of Pathology* (26:77 [July] 1938). These men had for many years consumed denatured alcohol with all its by-products. They preferred it with at least 5 per cent methyl alcohol, if 5 per cent methyl alcohol was not present they didn't think they were getting a kick out of it. On one occasion, through an indiscreet sale of pure methyl alcohol they consumed varying quantities from 200 cc to a pint (475 cc). Fatty changes were present in all of the livers but in only one was there the slightest trace of cirrhosis, a typical periportal cirrhosis. Several years ago I had occasion to analyze the incidence of cirrhosis among 5,000 autopsies and similar facts were present.

DR A. J. CARLSON, Chicago. May I make a plea for more accuracy in presentations and discussions? The speaker referred several times to alcohol causing cirrhosis. That is an old question, but it obviously depends on the quantity of alcohol. When a speaker refers to experimental alcoholism in dogs or other animals, let him cite the quantity of alcohol in twenty-four hours, so that the members may have something to go by, not just a general term, as if a sniff of alcohol at a distance of a hundred feet will produce cirrhosis of the liver. I think it is incumbent on contributors to get quantitative relations, particularly if they publish their results, and it won't hurt them even when they talk.

DR CHARLES L. CONNOR, San Francisco. Of course I did not say that alcohol is the only thing which will cause cirrhosis, but exactly the opposite. I said that large amounts of alcohol are necessary, and the amount of alcohol that men can take varies greatly. Many men get a tolerance to alcohol, which I think means that they get accustomed to a lower respiratory quotient, just as a man may become accustomed to a protein and fat diet and get along well. Other things which I mentioned briefly will cause fatty cirrhosis of the liver

—among them diabetes and some of the poisons which are similar to alcohol in their action, a cirrhotic liver which has not been previously fat may become fatty toward the end. As patients do not eat during the last few days of their lives, fat will infiltrate into the liver. Frequently at postmortem examination persons are shown not to have eaten or assimilated food for the last three or four days. The fatty liver of that sort is of no importance. The men that Dr Menzie mentioned, who died without cirrhosis, represent the first group which I mentioned, they manifest the inevitable mortality of alcoholism during the experiment in man himself. Methyl alcohol, and perhaps even gasoline, which some of the patients here have been drinking, will cause similar fatty changes. Dogs die in that stage, or any other animal will die in that stage, and the experiment in dogs is attended by a high mortality. If they live long enough, however, they will get a fatty type of cirrhosis. The difficulty with man as well as with animals has been to have them live until they get the cirrhosis. I did not have time for details. I condensed a large amount of work into a short paper. Most of my data on the respiratory quotient of the liver came from physiologists who have published it in textbooks or papers. The amount of alcohol that the dogs got varied from 50 cc of 40 per cent alcohol downward. After the livers became fatty the dogs could take considerably less, and my object was to keep them saturated and at the same time to keep them alive, so that absolutely quantitative methods could not be followed.

## RESECTION OF SUPERIOR HYPO GASTRIC PLEXUS AND SACRAL SYMPATHETIC GANGLIONS

FOR THE RELIEF OF PAIN IN THE BLADDER

CARLISLE F. SCHROEDER, M.D.

AND

ROBERT E. CUMMING, M.D.

DETROIT

The present status of treatment of incurable tuberculous cystitis as well as pain arising in the bladder in general, and especially the rather discouraging opinions that can be gleaned from the literature with regard to its treatment by superior hypogastric (presacral) neurectomy, lead us to report our results in a series of cases of intractable painful cystitis in which relief was obtained by the use of pelvic sympathetic surgery.

The treatment of this distressing condition in the past has been only moderately successful and is used in only a relatively small number of the patients affected. The newer knowledge of the nerve pathways to and from the bladder, as well as recent concepts of the physiology of the bladder in man, has made it possible to relieve greatly not only pain arising in the bladder but also other symptoms, such as frequency and nocturia associated with it. All types of treatment of painful and tuberculous cystitis have been well covered in textbooks and the periodical literature.<sup>1</sup>

Dr. Cumming died June 22, 1938.

Attempts to relieve pain arising in the pelvis by sympathetic surgery are not new. The work of Jaboulay<sup>2</sup> in 1898 toward this end is now being given due credit. Jaboulay, believing that pain from the pelvic viscera might reach the central nervous system through the sympathetic nerves, sought to cut the same communicantes of the sympathetic chain by a retrorectal approach. His operation was partially successful because of the lack of accurate knowledge of the pelvic nerve supply. Latarjet<sup>3</sup> in 1913 gave a more adequate description of the nerve supply of the pelvis and described further the "presacral nerve," which now often goes by his name. Winslow, however, is given credit for the first description of this group of nerves in 1732. It was not until 1921 that sympathetic surgery was again systematically directed toward the relief of pelvic pain. In that year Rochet<sup>4</sup> did perineurectal sympathectomies, believing that the pain in tuberculous cystitis was due to spasm originating in the lower ureters. He reported three cases, one with some relief of pain, but in all there was incontinence and the operation was abandoned. In spite of the earlier description of the "presacral nerve" (superior hypogastric plexus), it was not until 1925 that Cotte<sup>5</sup> first employed presacral neurectomy (Cotte's operation) for the relief of pelvic pain, reporting numerous gynecologic cases of pelvic pain since that time, in the large majority of which the patient was entirely relieved by the operation. One year later (1926) Pieri<sup>6</sup> used presacral neurectomy for the relief of pain in the bladder in tuberculous cystitis; he had, however, only mediocre results in his first case. He then added sectioning of the sacral rami communicantes and the dividing of the sacral sympathetic chains at the level of the first sacral segment. The results of the latter operation were far superior.

Learmonth<sup>7</sup> in 1930 applied Cotte's operation (resection of the presacral nerve only) to paralytic bladders. He proved on human beings subjected to this type of surgery definite physiologic facts on which the operation is based. By arranging cystoscopic examinations at the time of operation his colleagues observed the changes following stimulation and division of the nerves in question.

The anatomy of the pelvic sympathetic nerves, supplying the bladder and posterior urethra, is rather intricate and has been thoroughly described in the literature,<sup>8</sup> so that only a brief outline is in order here (fig 1).

The bladder and posterior urethra receive their nerve supply from three sources: somatic, sympathetic and parasympathetic (figs 2 and 3).

The somatic nerves carry both motor and sensory fibers to the bladder and posterior urethra by way of the pudic nerve, derived from the anterior division of the third and fourth sacral nerve roots.

The sympathetic nerve supply is derived from the thoracolumbar system and is divided into three groups as to location and source: right lateral, middle and left lateral plexus trunks derived from the celiac, renal, mesenteric and first four lateral lumbar sympathetic chain ganglions. The latter are preganglionic medullated fibers and represent more than half of the fibers of the superior hypogastric plexus, all the former being postganglionic nonmedullated fibers. These plexuses are "bottle necked" in the region of the last lumbar vertebral body to form the so-called presacral nerve (superior hypogastric plexus), which in turn divides into two definite hypogastric nerves that course through the hypogastric ganglions (two large flattened ganglions on the lateral aspects of the rectum) and hence to the

Fig. 1—Anatomy of the pelvic sympathetic nerves supplying the bladder and posterior urethra.

bladder. The superior hypogastric plexus has many variations.<sup>9</sup> It receives branches from other regions from the inferior mesenteric plexus, from the last ganglion from the lumbar chain<sup>10</sup> and from the first sacral ganglion as shown by Douglass.<sup>11</sup> Mueller<sup>12</sup> shows also several branches to the lateral sacral sympathetic chain at various levels. Our own dissections have shown these to be variable. Anatomists working with preserved cadavers in the dissection room have as a group shown the superior hypogastric plexus more as a conglomerate nerve, whereas surgeons and those working with live tissue, and our own work with fresh cadavers, reveal a plexiform group with several fine fibers to and from the lateral sacral chain. As shown

by Elaut,<sup>10</sup> it in most cases is not a "nerve" but a plexus and not presacral in location but opposite the fifth lumbar vertebral body. The presacral nerve, therefore, should rightfully be called the superior hypogastric plexus, which name has become standardized, although it has had numerous other names since its first description.<sup>13</sup>

Fig 2—Diagram showing nerve supply of the bladder and posterior urethra

The parasympathetic fibers take their origin from the anterior primary divisions of the second, third and fourth sacral nerves.<sup>14</sup> They emerge as three roots and form the so-called pelvic nerves to the bladder, course to the hypogastric ganglions (which consists mostly of pelvic nerves as shown by degeneration experiments, and therefore would better be called pelvic plexus), finally lose their medullary sheaths and are divided into three roots as follows:

- 1 Upper root going to the fundus of the bladder
- 2 Middle root going to the midportion of the bladder
- 3 Lower root going to the lower aspect of the bladder, supplying the vesical neck and the first portion of the urethra

The basic physiology concerned with the nerve supply of the bladder, as with sympathetic physiology generally in man, lags behind the surgery of the system. Head,<sup>15</sup> Learmonth,<sup>16</sup> Aburel and Kapri<sup>17</sup> and McCrae

and McDonald<sup>18</sup> have probably done the most work clinically and experimentally along this line. Learmonth and Braasch found by simultaneous cystoscopy and laparotomy with exposure of the superior hypogastric plexus that the sympathetic nerves brought about closure of the ureterovesical orifices, contraction of the trigon, closure of the internal sphincter, contraction of the prostate, seminal vesicles and ducts, and inhibition of the expulsive power of the bladder, and that they carried afferent fibers for sensation in the bladder. It has been noted also that the parasympathetic system brought about initiation and augmentation of the contraction of the bladder and inhibition of the internal sphincter, afferent fibers of the micturition reflex and afferent fibers for the sensation of pain in the bladder.

Summarizing the motor relations, Rose<sup>19</sup> calls the sympathetic nerves the "nerves of accommodation of urine" and the parasympathetic the contracting or "emptying" nerves of the bladder. Jaboulay called the presacral nerve the "brain" of the pelvic sympathetics. Both systems, as pointed out, carry sensory fibers, the majority of which are carried by the parasympathetics, although sensory fibers also course through the sympathetic (superior hypogastric plexus) group, as shown by Learmonth<sup>20</sup> who cites a case of total paraplegia in which the patient had some sensation in the bladder. It has been further shown by Pi-Suñer and Raventos<sup>21</sup> that section of one system does not abolish sensibility in the bladder.

Recent work by many observers, especially McCrae and McDonald,<sup>18</sup> reveals doubt as to whether one system is exclusively excitator and the other inhibitor in

Fig 3—Schematic diagram showing nerve connections.

function or that they are antagonistic. They admit, however, that the sympathetic and parasympathetic nerves work together with the pudendal nerves in regulation of the bladder. Most observers agree that the parasympathetic nerves are the most important. McCaughan,<sup>22</sup> quoting Gruber, states "that the bladder

is enervated by the sympathetic and parasympathetic, each supplying both motor and inhibitory impulses, and that there is no difference between the effect of these two systems except the possibility that the parasympathetic nerves carry stronger impulses."

With these facts in mind, we attempted to perform a more radical sympathectomy than Cotte's presacral neurectomy and Pieri's division of the sacral sympathetic chain and rami communicantes. This we accomplished by doing an excision of the superior hypogastric plexus and, in addition, excision of the sacral sympathetic chains including the first second and third sacral ganglions with all their connections. The latter procedure is similar to the phrenico-exeresis of Felix,<sup>23</sup> which he proposed in 1924 for a more complete and lasting paralysis of the diaphragm. Felix's operation today is little used because of the permanence of diaphragmatic paralysis the very thing we are striving for in this type of operation. The combined operation itself, excision of the superior hypogastric plexus and

Fig 4—Simple excision of the superior hypogastric plexus (Cotte's operation)

lateral sacral ganglions, is only slightly more difficult, technically, than excision of the superior hypogastric plexus alone (figs 4, 5 and 6)

Also, having in mind the work of Jaboulay, Rochet and Pieri, the former two in human and the latter, as well as others, in animal experimentation which indicated that complete severance of the autonomic system to the bladder is followed by incontinence, we attempted a more radical sympathectomy by exeresis of the lateral sacral chain along with excision of the superior hypogastric plexus, thus endeavoring to obtain more lasting results. We still leave intact most of the parasympathetic fibers as well as the pudendal somatic supply. In order to remove the sensory fibers of both these groups and not the motor (which had always been done with nerve resections, resulting in incontinence) we have added, when necessary, the postoperative use of intrathecal alcohol, with careful exacting control of the subarachnoid dispersion (fig 7). This does not result in paralysis but does give relief of pain and cessation of frequency. The sensory fibers in the superior hypogastric plexus are diffused over a larger area in the cord and are not well adapted to intrathecal alcohol (renal, celiac, mesenteric and lumbar sympathetic

chain). These fibers are conveniently attacked by surgery, since they are "bottle necked" over the fifth lumbar vertebra in the form of the superior hypogastric plexus, as stated Dogliotti<sup>24</sup> first suggested and used subarachnoid alcohol for the relief of intol-

Fig 5—Excision of the superior hypogastric plexus section of sacral sympathetic chain and rami communicantes (Pieri's operation)

able pain and it has been suggested by others for the relief of pain resulting from tuberculosis of the kidneys and bladder.<sup>25</sup> Intrathecal injection of alcohol, although simple, is not without danger. Numerous accidents and sequelae have been recorded.<sup>26</sup>

Fig 6—Excision of the superior hypogastric plexus exeresis of the sacral sympathetic chains

The technic of the injection of alcohol for this type of subarachnoid dispersion is as follows. A spinal tap is carried out as low down as possible in the spine

It is important to suffuse the most caudal continuation of the dural sac, since only the sacral nerves are to be necessarily affected by the injection Stern<sup>27</sup> has shown that injections in between the spinous processes of the second and third lumbar vertebrae are more apt to be followed by paresis of the bladder than injection

Fig 7—Excision of the superior hypogastric plexus excision of the sacral sympathetic chains followed by intraspinal alcohol

one level higher, when the lateral prone position is used We suggest, and have used in most cases, a lateral prone position with the buttocks high and the torso rotated anteriorly—an oblique position—and make the spinal tap as low as possible From 0.5 to 1 cc of absolute alcohol is used and the injection is given very slowly, the patient being kept in the exaggerated position described for three hours and then in a face down prone position for an additional three hours No vesical or rectal paralysis has resulted from these injections We have had patients with transient paralysis of the bladder and even transitory weakness of the leg by using a higher level and not keeping the patient in the exaggerated position with the torso rotated anteriorly

The technic of the combined operation is similar to that described by Pieri<sup>6</sup> and others,<sup>28</sup> except that the sympathetic chain is divided as in Pieri's operation, the proximal end of the distal segment is then grasped with a hemostat and the instrument is rotated, the nerve being wound on the clamp and at the same time the chain being gradually freed with a blunt instrument from all its attachments to or below the third sacral segment

This more radical denervation causes a significant change in the physiology, so that there has been slight disturbance of micturition with temporary postoperative incontinence but never retention requiring catheter-

ization as reported by other authors<sup>29</sup> Other effects, such as loss of ejaculation but retention of orgasm, in males correspond directly with other cases reported Although in all our female cases pregnancy is contra indicated, it has been shown experimentally by Rosselli<sup>30</sup> and clinically by Cotte and others that there is no disturbance in the female organs of reproduction There is a retention of the feeling of pleasure which normally accompanies evacuation of the bladder

COMMENT ON CASES REPORTED<sup>31</sup>

In the literature and in reviewing our own cases we were impressed with the following facts

1 Temporary results are reported, lasting only a short time, from simple excision of the superior hypogastric plexus alone

2 Results from simple resection of the superior hypogastric plexus are varied with regard to beneficial effect

3 Uniformly poor results in applying excision of the superior hypogastric plexus to relieve the symptom of interstitial cystitis are reported The results are relatively poor even with excision of the superior hypogastric plexus and the lateral sacral chains, as shown by case 8

We have purposely delayed reporting our own results until sufficient time has elapsed to show that the results are relatively permanent For example, in case 1 resection of the superior hypogastric plexus and lateral chains was performed July 1934, lacking approximately one month of being four years, and with lasting results Variations in results from excision of the superior hypogastric plexus alone, as reported in the literature, probably are due to differences in the anatomy of the plexus itself, not all fibers being excised, such as branches going from the lateral sacral chains and to the plexus of the inferior mesenteric artery, or its con

crepancy in results in cases of tuberculous cystitis, as compared to those of interstitial cystitis, can be explained on the following basis. In tuberculous cystitis the lesions are notoriously on the trigon and about the ureteral orifices, whereas in interstitial cystitis the visible lesions are found most frequently on the anterior wall, the position of the elusive ulcer of Hunner, or in almost any other part of the bladder. The trigon apparently never is involved, as stated by Hinman.<sup>32</sup> The nerve supply also varies as to the portion of the bladder supplied, the sympathetic (superior hypogastric plexus) group supplies the region of the trigon more exclusively with motor fibers (Macht [1918] with drugs and Learmonth [1931] with stimulation) and it is reasonable to suppose that the sensory distribution is similar, whereas the parasympathetic nerves are concerned more with detrusor stimulation in all parts of the bladder except the trigon and carry most of the pain fibers, so that, in lesions of the bladder not especially prominent on the trigon, section of the sympathetic group is not sufficient even when sympathectomy is more complete, as with the operation described (resection of the superior hypogastric plexus and lateral sacral chains).

This may shed light on a trophic or nervous origin of the lesions in interstitial cystitis. The pain of tuberculous cystitis may be on a basis of trigonal or ureteral spasm, and removal of the sympathetic supply may influence them and thus alleviate the pain by relaxation of the vesical orifice and trigon. Based on the foregoing facts, we have therefore used injection of alcohol intrathecally along with sympathectomy for controlling the sensory components of the parasympathetic and pudic nerves when lesions are present over the entire bladder or posterior urethra and not confined to the trigon or thereabouts. Intrathecal (intraspinous or subarachnoid) alcohol, as procaine and other anesthetics, shows a selected action for sensory nerve tissue. The effect of alcohol or any of the other nerve-paralyzing drugs is not without danger and should be used only in cases of intractable pain when an accurate diagnosis has been made and confirmed and when no other measures after long intensive use have given relief.

#### SUMMARY

We do not condemn simple excision of the superior hypogastric plexus for other conditions such as neurogenic imbalance. We, like Learmonth and Braasch,<sup>33</sup> have had good results with simple excision in these neurologic cases. It has also been reported used by Richer<sup>34</sup> for atony of the vesical neck and by Abbott<sup>35</sup> for atony of the bladder and intestine, as well as by others for interstitial cystitis,<sup>36</sup> chronically infected or contracted bladder,<sup>37</sup> cancer of the bladder<sup>38</sup> and spastic

irritable bladder,<sup>39</sup> with varying degrees of success. Cotte,<sup>40</sup> however, reports a case in which there was cystalgia accompanied by dysmenorrhea in which resection of the superior hypogastric plexus relieved the dysmenorrhea but the cystalgia persisted and was relieved only by denervation of the vesical neck. Ward<sup>41</sup> reports its use in hydro-ureters with good results. It

Fig 9 (case 10).—Recurrent symptoms of bladder tuberculous seven years after nephrectomy. Complete relief of pain and frequency followed resection and alcohol injection.

has also been advocated by Adson<sup>42</sup> and Craig<sup>43</sup> as an additional procedure in sympathectomy for Hirschsprung's disease. It has probably been used more widely in gynecologic conditions than in any other. Since Cotte<sup>5</sup> first advocated it he has done it in hundreds of cases with good results. Similar results have been obtained by many other operators for all types of gynecologic disorders including dysmenorrhea,<sup>44</sup> pelvic neuralgia,<sup>4</sup> obscure pelvic pain,<sup>45</sup> chronic pelvic inflammatory disease,<sup>46</sup> dysmenorrhea with severe bleeding,<sup>47</sup> kraurosis vulvae<sup>48</sup> and carcinoma of the uterus.<sup>49</sup> Likewise, in general surgery the pain arising

from carcinoma of the rectum has been reported greatly relieved by its use.<sup>50</sup> Cotte<sup>51</sup> and Dechaume,<sup>52</sup> by careful microscopic studies of cases in which there was relief from dysmenorrhea and no other reason discernible to cause it, have found definite evidence of inflammation in and around the excised plexus throwing light on the etiology of so-called essential dysmenorrhea. Heitz<sup>53</sup> points out that resection of the superior hypogastric plexus for gynecologic pain usually is a benign operation giving relief with castration.

#### CONCLUSIONS

1 The literature is inclined to be slightly misleading with regard to the value of sympathetic surgery for the relief of pain in the bladder and frequency in incurable tuberculous cystitis and in other intractable and disabling conditions of the bladder.

2 Results of our operative cases show significant and lasting improvement.

3 The literature has shown that excision of the superior hypogastric plexus alone does not suffice in all cases, and the results of our operations have strengthened the hypothesis of this theory.

4 We therefore recommend excision of the superior hypogastric plexus and excision of the lateral sacral sympathetic chains.

5 Intrathecal (subarachnoid) injection of alcohol with controlled dispersion is a great adjunct to surgery and is probably related to the disruption of the parasympathetic and somatic pain fibers.

7815 East Jefferson Avenue

#### ABSTRACT OF DISCUSSION

DR ALEXANDER B HEPLER, Seattle. For the relief of pain presacral neurectomy alone might be expected to fail in a large percentage of cases because only a portion of the afferent fibers are contained in the hypogastric nerves. Although removal of additional sensory pathways through the lateral sacral sympathetic chain may give improved results, it will still fall short of complete relief in many cases, because of the afferent fibers in the parasympathetic and the somatic pudic nerves. It is difficult and undesirable to sever the latter nerve pathways to the bladder, because they contain not only other afferent fibers that are important in reflex functions but also motor fibers. For this reason Drs Schroeder and Cumming, in an attempt to remove only the important sensory fibers in these roots, have injected alcohol to get a sensory paralysis without a motor paralysis. This is possible because alcohol will affect the sensory nerves before it will the motor, not because it has any special affinity for sensory nerves but because in the sacral roots the pain fibers are more peripherally located and less heavily myelinated, so that they will be affected first. The extensive procedure of Drs Schroeder and Cumming is based on sound principles. However, I want to emphasize that much of the uncertainty which surrounds operations on the sympathetic trunks of the bladder for pain can be removed by the simple diagnostic test, before operation, of anesthetizing the pathways that one proposes to interrupt, with procaine hydrochloride. In this way one can tell not only how extensive a sympathectomy is indicated but whether or not any will work. Into the superior hypogastric plexus and the presacral nerves is injected 10 cc of a 2 per cent solution of procaine hydrochloride, according to the method described by Flathow. The injection is made at the level of the fourth lumbar interspace, about 7 cm from the median line, the needle is passed in at an angle of about 45 degrees to the upper portion of the body of the fifth lumbar vertebra and is then

passed in for about 15 cm along the anterolateral surface of the body of the vertebra, and 10 cc of procaine hydrochloride is injected. This is done on both sides. If the diagnostic injection is made at the time the patient is experiencing pain and the pain is relieved, presacral neurectomy alone can be done with assurance that it will almost certainly give complete relief from pain. If this injection does not relieve pain, low spinal anesthesia is given at the same level as the proposed intrathecal injection of alcohol. This will anesthetize the parasympathetic fibers in the second, third and fourth sacral roots and the somatic fibers in the third and fourth. If this alone relieves pain, laparotomy should be unnecessary. It would seem that if a large portion of the afferent sensory fibers pass through the parasympathetic and somatic nerves, as the authors have contended, or at least if the impulses are stronger, an intrathecal injection of alcohol alone should suffice in a larger percentage of cases than presacral neurectomy alone or the combined operation. If the pain is not relieved by either of the injections alone but is relieved when they are combined, one at least has some assurance that the combined operation will be successful. If the combined injections do not relieve pain, the suspicion is aroused that the symptoms are psychogenic.

DR J C NEELEY, Glendale, Calif. I was hopeful that a large number of cases could be found in a urologic clinic which had 12,232 hospital admissions in ten years and a sanatorium for tuberculosis which had 9,200 patients in sixteen years. The eight cases I present are all that I found. Of the eight cases there were four of interstitial cystitis. The first patient, a woman aged 39, had pain, burning and frequency for four years. This patient had undergone sympathectomy, appendectomy and removal of a cystic ovary, with about 30 per cent relief two years after operation. The second patient, a woman aged 39, had pain, burning and nocturia for four years. She had about 40 per cent relief two years after operation, and then after a course of sulfanilamide her relief increased to about 80 per cent and her nocturia entirely disappeared. Of the two patients with tuberculous cystitis, one, a man aged 24, had pain and almost continuous voiding for a period of about eight months. He had about 30 per cent relief. He died three months later of rupture of the bladder. The other, a woman aged 32, had pain and frequency (voiding every thirty minutes) for about a year. She obtained about 40 per cent relief from her symptoms but died in eight months of acute miliary tuberculosis. All these patients had complete operations in that all the visible fibers were removed for an appropriate length and there was complete denudation of all the blood vessels for a considerable distance from the anatomic location of the nerve plexus. The object of any operation is cure of the abnormality or relief of distressing symptoms to approach as near to 100 per cent as possible. If more than 50 per cent relief cannot be offered by an elective operation, such operation, in my opinion, is unwarranted.

DR REED M NESBIT, Ann Arbor, Mich. At the University Hospital I have performed sympathectomy for relief of vesical pain in six cases. The types of vesical pain must be differentiated. Two patients had severe tuberculous cystitis and four had nontuberculous cystitis of long standing, at least five years for each, which was refractory to all other types of treatment. Three of the patients had the combined operation described by the authors, resection of the superior hypogastric plexus and excision of the lateral sacral sympathetic chains. Three had presacral sympathectomy alone. All patients had complete relief of vesical discomfort. All the nontuberculous patients showed clear urine a few weeks postoperatively without medication. I don't know why that happened. Cystometric examinations at least one month postoperatively in all six cases showed (1) normal control over micturition, (2) increase in capacity of the bladder, (3) normal sensation for temperature and filling and (4) the sensation of overdistention, produced by pain exactly as in normal subjects. Cystoscopic examinations of all patients performed at least one month postoperatively, showed slight improvement in the cystitis in cases of tuberculosis and remarkable improvement in the appearance of the mucosa in nontuberculous involvement. In one of these cases, that of a woman who had been in my hands for ten years for treatment of non-tuberculous cystitis, I myself had made cystoscopic examination during spinal anesthesia six different times and had never seen the ureteral orifices. One month postoperatively one of my

assistants observed a normal cystic mucosa and catheterized both ureters. Previous to that time the bladder looked like a piece of raw beefsteak. In all six cases there was normal tactile sensation in all parts of the bladder and electrical stimulation of all parts of the bladder produced pain, as it did in the normal subject. From these observations it is obvious that normal afferent components exist after sympathectomy. It would therefore appear that the relief of the spasmodic pain of cystitis which follows sympathectomy results from the interruption of vasoconstrictor fibers in the presacral nerves, allowing relief of muscular or vascular spasm in the bladder. If this is true, one would expect relief of pain in cases of cystitis, one would not expect it in cases of Hunner ulcer or of cancer of the bladder.

## UNDESCENDED TESTES

### PRESENT STATUS OF GLANDULAR TREATMENT

WILLARD O THOMPSON, M.D.

AND

NORRIS J HECKEL, M.D.

CHICAGO

In a recent communication to *THE JOURNAL* we<sup>1</sup> demonstrated that the anterior pituitary-like principle from the urine of pregnant women may produce such marked stimulation of genital growth in young boys that a syndrome resembling premature puberty results. The present paper is concerned with the influence of this material on undescended testes.

Since Schapiro's<sup>2</sup> report eight years ago, the anterior pituitary-like principle has been used extensively in the treatment of this condition. In spite of numerous observations in other clinics showing a high incidence of successful results, we have consistently been unable to produce descent in most instances of true cryptorchidism.<sup>3</sup> In order to explain this discrepancy a critical survey of the problem is desirable. An analysis of the results of other observers<sup>4</sup> is given in table 1.

From the Departments of Medicine and Surgery, Rush Medical College of the University of Chicago and the Presbyterian Hospital. Owing to lack of space this article has been abbreviated. The complete article appears in the authors' reprints.

Read before the Section on Practice of Medicine at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

It may be seen that there were 860 undescended testes in 579 patients. The condition was bilateral in 281 and unilateral in 298. Of all the undescended testes, 524, or 61 per cent, descended. These successful results may be divided according to the original position as follows: intra-abdominal, descent reported in eighty-three of 150 cases, or 55 per cent; inguinal, descent reported in 172 of 298 cases, or 58 per cent; in upper part of scrotum, descent reported in fifteen of seventeen cases, or 88 per cent; and location unstated, descent reported in 254 of 395 cases, or 64 per cent.

In our<sup>5</sup> series only 20 per cent of all the testes descended, and descent occurred in only 27 per cent of the patients under 16 years of age (table 2). The difference between the high percentage of successful results reported by most other observers and our own percentage may be attributed in part to our exclusion, except in the beginning of the study, of all testes of the migratory or retracted types.

### IMPORTANCE OF ACCURATE DIAGNOSIS

Migratory testes, namely those which move back and forth readily from the canal to the scrotum, are not true undescended testes and tend to remain in the scrotum after puberty. In studying patients referred to us for treatment, we have been impressed by the large number of testes of this type which were considered to be true undescended testes. In distinguishing between true cryptorchidism and pseudocryptorchidism it is important that the examiner have a thorough knowledge of the pathologic anatomy of undescended testes and that the testes be carefully manipulated on more than one occasion with the patient in the upright position. The location of an undescended testis cannot be determined accurately with the patient in the recumbent position, and a testis cannot be considered intra-abdominal unless it is impossible to palpate it by any method of examination. A testis which appears to be in the abdominal cavity in the recumbent position is often found in the inguinal canal in the erect position.

\* Unless otherwise noted, the references cited in this table are listed in footnote 4.

† The data of Dahl Iversen and Sturup Schapiro and Mimpriss (1935) are not recorded in a manner that makes it possible to incorporate them in this table. The first authors reported a high percentage of successful results from the use of several preparations and considered glandular treatment preferable to operation, while Mimpriss noted only four instances of descent in fourteen patients and was skeptical about the value of such treatment.

distinguished from those in the inguinal canal by the fact that they lie more superficially and can be moved readily under the skin. Those in the upper part of the canal can often be displaced into the abdominal cavity. It will be shown later that the location of the testis has an important bearing on the response to glandular treatment.

#### ANALYSIS OF OUR RESULTS

It may be seen from table 2 that the effect of treatment was observed in fifty undescended testes in thirty-eight patients. Except for a few of the older patients

was unsuccessful and the testis could not be palpated. Thus the condition was originally bilateral in fifteen of the thirty-eight patients and unilateral in twenty-three. In fourteen in whom the condition was unilateral to begin with, the undescended testis was on the right side, and in nine it was on the left. As a result of treatment with the anterior pituitary like principle from the urine of pregnant women, ten testes (five on each side) descended in nine patients (table 3). Thus the incidence of successful results was 20 per cent on the basis of the number of undescended testes and twenty-four per cent on the basis of the number

of patients. It appeared to be easier to produce descent before than after the age of puberty. In twenty-eight patients under 16 years of age descent occurred in nine of thirty-three undescended testes (27 per cent), whereas in ten patients 16 years of age and over it occurred in only one of seventeen undescended testes (6 per cent).

Fig 1 (H S)—Genital growth from the anterior pituitary like principle with descent of the right testis. No growth was observed until after the testis had reached the upper end of the scrotum. There was associated hypospadias. A taken Aug 24 1936 before treatment at the age of 7 years. B taken June 1 1937 after 7 600 rat units of follutein followed by 43 800 rat units of A P L had been given.

In three patients (R B, A V and W T) the testis could be displaced into the scrotum before treatment was started, and these patients really should not be included in this series. They were incorporated in our original report<sup>3</sup> to give the treatment the benefit of the doubt. Their exclusion would leave only seven instances of descent for forty-seven undescended testes (15 per cent).

Descent occurred in eight cases within two months after treatment was started and in the other two within four months and twenty-one months respectively. The patient who showed descent at the end of four months was 23 years old and at first was given a dose too small to produce genital growth. The patient (D B) requiring twenty-one months for descent was 10 years old and showed less susceptibility to the stimulus than many other patients. His left testis was in the fold of skin to the left of the scrotum, and it was not until genital growth had been produced by the administration of large doses that it appeared in the upper end of the scrotum.

The position of the testis appeared to be an important factor in determining the result of treatment.

Descent was produced in nine of twenty-one instances (43 per cent) in which the testis was in the inguinal canal, in only one of nine instances (11 per cent) in which it was deflected in an abnormal position outside the canal and in none of the twenty instances in which it was within the abdominal cavity. The only patient in whom descent was produced when the testis was deflected in an abnormal position was D B, previously referred to, in whom the testis was deflected in the fold of skin to the left of the scrotum. Descent was not produced in any instance in which the testis was deflected over the external oblique muscle or toward the base of the penis. In one boy 7½ years old we thought at first that we had caused both testes to move from the abdomen into the scrotum, because we did not feel them before treatment was started. Their descent within three weeks after treatment was started seemed so remarkable to us that we explored the matter further. On questioning his mother, we found that from the time of the child's birth she had frequently seen and felt both testes in the scrotum, while at other times they were not there. When we made our first examination the boy was greatly embarrassed and it is possible that the emotional reaction resulted in the retraction of the testes into the abdominal cavity. There can be little doubt that these testes were of the migratory type, and we have excluded them from this series. Our failure to produce descent in our cases of intra-abdominal testes is in striking contrast to the results of some other observers (table 1). In five of our ten successful cases the testis could either be pulled into the upper end of the scrotum or to a level between the lower end of the canal and the upper end of the scrotum before treatment was started. In other words, the testes were of the type that commonly descends at puberty. In the other five cases there could be little doubt of the influence of the treatment in causing descent.

Fig 2 (H S)—A taken Aug 24 1936 before treatment and B taken June 1 1937 after treatment.

More striking than descent of the testis was the production of genital growth in seventeen of thirty-one patients who received the medication for a long period. Growth without descent occurred in ten patients, while descent without measurable growth was noted in seven (figs 1 to 4). However, in three of these seven patients (H S, A V and W T) the genitalia grew later with continued medication.

In our unsuccessful cases the average dose was much greater than that in our successful cases. Thus failure to produce descent in a larger number of cases cannot be attributed to lack of adequate dosage. The production of genital growth without descent of the testis in ten patients is further proof of this point.

#### TREATMENT FOLLOWING UNSUCCESSFUL ATTEMPTS AT SURGICAL CORRECTION

The effect of treatment was observed in six boys from 7 to 13 years of age in whom it had not been possible to bring the testis to a sufficiently low level at the time of operation. In five boys the testis was

TABLE 3—Analysis of Successful Cases

Patient	Age Years	Position of Testes		Time Required for Descent	Genital Growth	Total Dose Required for Descent Rat Units
		Before Treatment	After Treatment			
A V	5½	Right, in scrotum Left in canal could be displaced easily to upper end of scrotum	Right in scrotum Left in scrotum	4 weeks	None until later	625 follutein
T D	6½	Right, at level of external ring associated with hernia could not be displaced downward	Right, at upper end of scrotum with hernial sac extending below Left in scrotum	7 weeks	Moderate (marked later)	1,570 follutein
H S	7 yr 11 mo	Left in scrotum Right in lower part of canal could not be displaced downward	Right, in upper end of scrotum Left in scrotum	9 weeks	None until later	4,400 follutein
O B	9	Right in inguinal canal Left in inguinal canal	Right in scrotum Left in inguinal canal	4 weeks	None or slight	2,125 follutein
R B	9	Right just inside external ring, could be displaced into scrotum Left in scrotum	Right in scrotum Left in scrotum	2 weeks	None	990 follutein
W T	10	Right just below external ring displaced into scrotum readily Left could be moved from level of internal ring to upper end of scrotum	Right, in scrotum Left, in scrotum	2 weeks 2 weeks	None until later	1,000 follutein
D B	10	Right, in scrotum Left in fold of skin beside scrotum could not be displaced into scrotum	Right in upper end of scrotum Left in scrotum	21 mo	Marked	14,400 follutein 6,100 A P L
F V	12	Right in scrotum previously undescended, but corrected by orchidopexy Left in inguinal canal could be displaced into abdominal cavity	Right in scrotum Left in scrotum	2 weeks	None	625 follutein
A B	23	Right not palpable (previous attempt at orchidopexy) Left in inguinal canal	Right not palpable Left in scrotum	4 mo	Moderate	5,000 A P L

TABLE 4—Observations at Operation in Eleven Unsuccessful Cases

Patient	Age Yrs at Beginning of Treatment	Position of Testes		Genital Growth	Total Dose Administered Rat Units	Observations at Operation
		Before Treatment	After Treatment			
R Bn	8	Right intra abdominal Left, in scrotum	No change No change	None	8,600 follutein in 3½ mo	Right testis just inside internal ring with peritoneal process protruding from external ring Left testis in canal bound down by fine connective tissue bands
M A	12	Right, in scrotum (right orchidopexy before treatment) Left intra abdominal	No change Left in upper part of inguinal canal	None	8,175 follutein in 4½ mo	Testis and peritoneal process deflected upward over external oblique muscle just lateral to ring
F G	8	Right, in scrotum Left deflected over external oblique muscle to a point 4.5 cm above base of penis	No change No change	None	4,900 follutein in 4½ mo	Testis just under external ring in the peritoneal pouch which extended downward and ended as a fibrous cord at neck of scrotum
L K	11	Left in scrotum Right in inguinal canal and could be displaced downward to opening above scrotum	No change No change	Marked	12,900 follutein in 8 mo	Testis in canal bound to peritoneal pouch and three fascial layers by connective tissue
C DIB	7	Left in scrotum Right in canal but could be displaced downward to upper part of scrotum	No change No change	Marked	5,440 follutein in 2 mo	Left testis in inguinal canal at external ring, peritoneal pouch lay over rectus sheath and extended to within 1.5 cm of neck of scrotum

in the opening just above the scrotum and in one could not be palpated. In one the condition was bilateral, making a total of seven undescended testes in these six boys. As a result of treatment, four testes descended and five boys showed marked growth of the genitalia. No descent occurred without genital growth, but marked genital growth occurred without descent in two boys.

#### OBSERVATIONS AT OPERATION

Eleven patients who failed to show descent had an orchidopexy (table 4). In every instance anatomic factors were found which prevented descent, and these were not corrected by glandular treatment. These anatomic factors were (1) fibrous bands (all patients), (2) shortness of the structures to which the cord and testis were attached, namely the peritoneal process, the transversalis fascia, the intercolumnar fascia and the cremasteric muscle and fascia (all patients), (3) abnormal direction of the peritoneal process (four patients), which in three patients was turned upward on the external oblique muscle and in one lay over the rectus sheath, and (4) absence of the external ring (one patient). In some instances shortness of the blood vessels of the cord appeared to be a factor.

Our results indicate that operative procedures are necessary in about three fourths of all cases of true cryptorchidism. This does not mean that treatment with the anterior pituitary-like principle is not of value. Even when it does not produce descent it may aid subsequent operative procedures, apparently by enlarging the parts involved. In each of the eleven instances cited in table 4 it was possible to bring the testis into the scrotum without injury to its blood supply.

#### SIGNIFICANCE OF OBSERVATIONS

The high percentage of failures in the treatment of true cryptorchidism with the anterior pituitary-like principle from the urine of pregnant women naturally raises the question of the value of this form of treatment. It has been well established that the incidence of undescended testes is much less after than before puberty.<sup>6</sup> This apparently means that the hormonal changes incident to puberty produce descent in a large percentage of cases. The difference in incidence in the prepubertal and postpubertal periods may be accounted for in two ways: (1) the inclusion of a large number of testes of the migratory or retracted type, which remain in the scrotum after puberty, as true undescended testes and (2) the descent at puberty of testes not retained by mechanical factors.

It would be interesting to know what the difference in incidence in the prepubertal and postpubertal ages would be if migratory testes were excluded. It is possible that the percentage of patients showing descent spontaneously at the time of puberty would be about the same as with the anterior pituitary-like principle given before puberty. As a result of treatment with this principle, we may cause descent only of those testes which would descend normally about the time of puberty. Influences similar to those which we have introduced artificially come into play as the result of normal development and might be expected to result in

descent of the testes when no anatomic abnormality exists. If we accomplish no more with this treatment in young boys than is accomplished by natural processes at a later age, we must inquire whether the treatment is worth while. The crux of the problem is whether a testis made to descend at an early age with treatment is more likely to be normal than one which descends later without treatment. The consensus appears to be that in true cryptorchidism the testis should be brought into the scrotum at an early age, although there is some difference of opinion on this point. Treatment with this material, by distinguishing between those cases in which descent is prevented by anatomic factors and those in which it is not, makes it possible to tell

Fig 3 (G A)—Genital growth from the anterior pituitary-like principle without descent of the left testis. A taken Nov. 8 1937 before treatment at the age of 6½ years. B taken April 28 1938 after 45 500 rat units of A. P. L. had been given.

early what patients will require surgical intervention. However, it should be pointed out that little is known about the effect of premature stimulation with this material on the function of the testis after puberty.

#### PRESENT STATUS OF TREATMENT

In the light of these observations it is important to maintain an open mind on the treatment of undescended testes with the anterior pituitary-like principle. Many reports appear to be overenthusiastic. If the importance of bringing the testis into the scrotum at the earliest possible age has not been overestimated, perhaps the wisest course is to administer this material cautiously and carry out operative procedures if descent fails to occur. Susceptibility to the anterior pituitary-like principle varies markedly, so that dogmatic statements about the size of the dose and the duration of

treatment cannot be made. As a rule, in successful cases descent of the testis occurs within two months after the daily administration of from 100 to 1,000 rat units is begun.

We have previously pointed out that genital growth produced by this material may be so marked that changes simulating premature puberty result,<sup>7</sup> and there can be little doubt that excessive genital growth should be avoided. It would be desirable to know what effect premature stimulation of testicular function by this material has on subsequent spermatogenesis, skeletal growth and social adjustment.

These considerations apply only to boys with uncomplicated cryptorchidism. When failure of descent of the testis is associated with hypogonadism, genital growth is to be desired and much larger doses may be administered over a much longer period.

#### SUMMARY

The effect of the anterior pituitary-like principle from the urine of pregnant women in the treatment of undescended testes appears to be exaggerated. With thirty-eight patients of all ages, descent was produced in only ten of fifty undescended testes, or in 20 per cent, compared with an average of 61 per cent of successful results reported in the literature. If only the twenty-eight patients under 16 years of age are considered, descent was produced in nine of thirty-three undescended testes, or in 27 per cent. Descent did not occur in any instance in which the testis was intra-abdominal or deflected over the external oblique muscle.

It follows that, in the majority of cases of true undescended testes, operative procedures are still necessary because of mechanical factors which prevent descent.

The administration of the anterior pituitary-like principle makes it possible at an early age to distinguish between those testes which require surgical intervention and those which do not. When the testis does not come down, the treatment may facilitate subsequent operative procedures by enlarging the parts involved.

The value of this form of treatment depends on the importance of getting the testis into the scrotum as early as possible. If early descent is important, the management of cases of undescended testes involves the intelligent combination of medical and surgical measures.

Treatment should be discontinued before genital growth becomes excessive.

In evaluating the effect of treatment it is important to exclude all cases of pseudocryptorchidism.

Many unsolved problems, such as the influence of premature stimulation of the testis on its function later in life, on skeletal growth and on social adjustment, make it necessary to preserve an open mind on the treatment of undescended testes with the anterior pituitary-like principle from the urine of pregnant women.

It is possible that this material causes descent only of those testes which would descend without treatment about the time of puberty.

#### ABSTRACT OF DISCUSSION

DR. HANS LISSER, San Francisco. Fully fifteen years ago in treating a number of boys with the Frohlich type of obesity by a reasonable regimen of weight reduction including the use of thyroid and whole pituitary combined in a coated capsule I noted descent of the testes every now and again. Of course the significance of it escaped me, because I never published a record of it, merely assuming that in the course of reduction and the taking away of the great pad of mons veneris in which the penis and tiny scrotum were concealed the testes came into view. In recent years I have used the gonadotropic principle to produce descent of the testes, but I find myself thinking in a different way than the authors. Rather than begin as early as possible, it seems to me much better to wait a reasonable time. But that I don't mean to wait until after puberty should normally have occurred, but I see no particular point in beginning the treatment until the boy has allowed nature to have a chance, namely until he is along about 12 or 14. Then I give the testes an impetus if they don't come down and stay down. I think that the authors are right in being conservative as regards statistics and calling attention to the many instances of migratory testes that are being classed as cases of cure. Of course, this matter of enthusiastic statistics is always the rule when something new comes along. I think it might be wise to wait until these boys get to be 12 or 14, and certainly the surgeon is not needed much before that. Furthermore, because of some of these extraordinary and convincing demonstrations of diminution I rather think sexual precocity might be avoided by waiting a little bit longer. Of course the authors, as they themselves stated, have used much larger doses than most observers, far more than I have used. I wonder perhaps whether some of the results might be attributed to a little too much of the substance.

DR. C. KOST SHIFTON, Los Angeles. The authors controlled their observations well, however I agree with Dr. Lissér wondering if it is rational to treat these patients early. I wonder what happens to the osseous development of such a child, and I should like to ask the authors if they have seen any definite advance in it. Epiphyseal closure is believed to depend somewhat on the sex elements. We know that the patient with spontaneous pubertas praecox is often an infantile giant, so to speak—an infant who grows more rapidly at that time and whose epiphyses close much earlier. They are also adult dwarfs, so to speak. It is possible that early treatment markedly alters the stature of the patient. I have never seen that occur, because I have never used doses as large as the authors have used. I have also felt that if these patients did not respond to a small dose of not more than from 1,000 to 1,500 rat units a week, of gonadotropic substance from the urine of pregnant women, over a reasonable period, I should not pursue the matter further. I have found, however, that the preparation will develop the penis apparently much better than it will produce descent of the testicles. I think the authors' statistics are about right, according to my series. It is well known that if one examines a patient on several occasions one frequently finds the testicles up at one time and down at another. I should like to ask whether the authors have ever found marked enlargement of the testicle intra-abdominally after administration of such large doses. I felt that the giving of large doses to patients with intra-abdominal testicles might produce actually such an enlargement that the testicles would not then later descend spontaneously. I have in a few instances seen a great deal of abdominal pain from this, and I feel that it has been due to the injections.

DR. WILLARD O. THOMPSON, Chicago. I am much obliged to Drs. Lissér and Shelton for bringing out points which we didn't have time to deal with in presenting the paper. Dr. Lissér raised the question whether it would not be wise to wait until a later age before starting treatment. As I understood him, he meant the age of 12 to 15 years. There are two reasons for that suggestion, one being that in some instances spontaneous descent occurs, and in some instances with the use of large doses of the substance changes simulating puberty occur. This question represents the crux of the problem. If it is true that we caused descent only of those testes which would descend

normally at the time of puberty, then the question arises as to whether there is any point in giving this treatment. If it is to be given, it should be given before the age of puberty, because at that time the changes which occur will cause descent if descent can be produced without operative intervention. The problem is how important it is to get the testes down at the earliest possible age. According to the results of Moore, it is important. We think there is some question about this and that a testicle which descends at puberty may perhaps be as well off as one which has been brought down at a much earlier age. If it is true that the testes should be brought down early, then the use of this material does make it possible to determine at an early age whether operative procedures will be necessary. It certainly is undesirable to produce changes simulating puberty in a boy anywhere from 3 to 7 years old. We presented examples of the powerful stimulus which this material exerts on the genitalia and examples of the fact that marked genital growth may occur without descent of the testes. This material may interfere with the function of the testes later in life. If it is true that treatment should be carried out early, it is also true, of course, that two thirds of the patients at least require surgical intervention, and it then becomes important to combine intelligently the administration of the substance with surgical procedures. Dr. Shelton raised the question of bony growth, the influence of premature sexual development on the epiphyseal closure. Our observations have been carried on for too short a time to allow us to answer that question. We have had the impression that boys showing marked genital growth have shown an increase in rate of osseous growth. What the eventual result will be we can determine only in the course of several more years. Dr. Shelton also raised the question of marked enlargement of intra-abdominal testes, preventing descent. By and large, we produced little increase in the size of testes in the patients we treated. If the testes were within the abdominal cavity, this material was much less effective in influencing either their function or their location than if they were in the canal or in the scrotum. We therefore think it improbable that the increase in size of a testicle within the abdomen from the use of this material would be great enough to prevent descent.

#### No Death from Dysentery in Africa in Italian Troops

—Dysentery has always been one of the worst scourges of armies in war time. During the great war the British Expeditionary Force in Gallipoli, consisting of 112,677 men and 4,161 officers, had during the campaign 29,728 cases of dysentery, with 811 deaths, more than a quarter of the whole force contracted the disease. During the Italo-Ethiopian War there was a total of 453 hospital cases of dysentery, with no death.

The great majority of cases were amebic. What prophylactic measures were taken? (a) Every effort was made to give the officers and men pure drinking water. Practically all the officers drank mineral waters bottled in Italy and shipped to Africa in gigantic quantity. I do not think there has been any war previously in which mineral waters have been used on so large a scale. Officers and men in warships and in hospital ships drank the noted Serino water, imported by cistern boats from Naples, where it is the normal city supply.

We could always get water by drilling wells deep enough. It was, of course, always boiled or chlorinated.

(b) The second prophylactic measure was this. The men were recommended to get into the habit of washing or disinfecting their hands with a 2 per cent solution of lysol or lysoform after visiting the latrine, and before having their meals. The lysol disinfection of the hands was strictly enforced on cooks and others working in the kitchens. In Somalia in many latrines and outside every kitchen was found a receptacle fixed to a post, containing a 2 per cent solution of lysol or lysoform.

No vaccines were used. With regard to dysentery oral vaccines, although my associates and I have worked on the subject for several years, I have not been able to convince myself that they are really efficacious—Castellani, Sir Aldo. Hygienic Measures and Hospital Organization of the Italian Expeditionary Forces During the Ethiopian War, 1935-1936, *J Roy Nat Med Serv* 24 304 (Oct) 1938.

## THE EFFECTS OF TUBERCULOPROTEIN

### A QUANTITATIVE STUDY

H J CORPER, MD

AND

MAURICE L COHN, PH D

DENVER

More than most other diseases, tuberculosis may be justly classed the disease of striking quantitative relations. Animals may survive large amounts of bacilli for a long time, while extremely small numbers of highly virulent mammalian tubercle bacilli will lead to progressive disease in the normal animal. Besides the variegated pathogenicity, these complicated relations may designate tuberculosis a mosaic disease. On numerous occasions in the past, uncertain and erroneous deductions have resulted when the quantitative relations of so simple a single factor as tubercle bacilli and their products have not been carefully weighed. An obvious basis for the experimental study of tuberculosis appears to be (1) the viable bacilli, (2) products derived from the bacillary bodies and (3) metabolism products, or the substances given off by the bacilli during growth or spontaneous disintegration. Prior to the past decade, the literature was encumbered by conflicting observations as a result of the lack of knowledge of the tubercle bacillus and the inability to obtain large amounts of chemically pure bacillary products. Regarding the former, it was contended for years that allergic hypersensitiveness could not be produced by heat-killed tubercle bacilli, while in recent years there has appeared to be a unanimous opinion in favor of such production.<sup>1</sup> Koch presented old tuberculin in 1891 for diagnostic purposes, and it still has advocates even though it contains extraneous proteins. On the other hand, the active principle has been prepared by cultural and chemical methods as a chemically pure tuberculoprotein by Long and Seibert<sup>2</sup> and can be studied scientifically.

Although chemical disintegration methods have been utilized for studying the constitution and biologic action of products of the tubercle bacilli,<sup>3</sup> within the past few decades, it appeared that in studying specific immunology it would be better to obtain an action from a pure product naturally produced and not denatured and to follow this activity quantitatively to its simpler forms, much as Long and Seibert did in studying and isolating the active principle of tuberculin. By utilizing virulent and avirulent mammalian tubercle bacilli (*Mycobacterium nusquam phymatosis*),<sup>4</sup> it was found<sup>5</sup> that

appropriate previous injections of avirulent human or bovine tubercle bacilli (given intracutaneously, subcutaneously or intravenously, but not enterally) retard the development of subsequent infection with virulent human or bovine tubercle bacilli. The effect is evident in the retardation of the disease in the local intracutaneous lesions and the tributary glands and in the metastatic organic disease developed. The immune effect develops definitely at the point where local macroscopic tubercles are produced by the intracutaneous injection of the avirulent tubercle bacilli.<sup>6</sup> In a continuation of these studies to obtain a better understanding of the mechanism of immunity in tuberculosis it was noted<sup>7</sup> that two apparently paradoxical conditions in tuberculosis under certain circumstances coexist and can be defined by quantitative evaluation and by using avirulent and virulent human and bovine tubercle bacilli. One of these, a specific immunity, is effective in retarding tuberculosis after virulent infections, as previously noted. It is associated with a changed tissue reaction, which is evident when the bacilli are given in amounts above the threshold of tubercle formation. The second condition—a type of protein intoxication, does not

indirect, since only the Dale uterus method was used for test of the biologic reaction. Therefore no definite quantitative factors could be noted. In 1931 Lewis and Seibert<sup>9</sup> found that the proteins isolated from filtrates of acid-fast bacterial cultures on a synthetic medium are actively anaphylactogenic. At this time they considered 20 mg. of protein to be the maximum amount that could be injected intravenously into normal guinea pigs without causing acute symptoms or death within forty-eight hours. Shortly thereafter, in 1932, Seibert<sup>10</sup> further approached the problem of sensitization to tuberculo-protein with pure preparation, and more accurate methods than Zinsser and earlier investigators used, but her investigations were not quantitatively exhaustive. These investigations were made possible by growing tubercle bacilli on Long's nonprotein synthetic medium and obtaining a pure tuberculo-protein by chemical precipitation, or ultrafiltration methods. Specific cutaneous sensitization was produced in normal rabbits and guinea pigs, for the first time, by repeated injections of the highly purified, undenatured protein of tuberculin. The sensitization was claimed to be of as high degree and of the same type

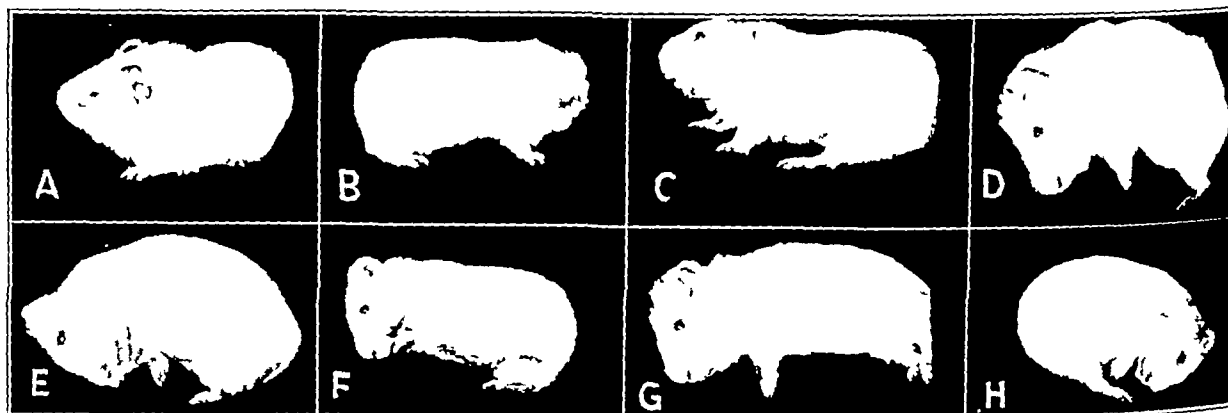

Fig 1—Anaphylactic shock resulting from the intravenous (ear vein) injection of 1 mg. of tuberculo-protein (the Seitz filtrate or the trichloroacetic acid precipitated protein from the growth of virulent human tubercle bacilli on a nonprotein synthetic medium) into a guinea pig previously given an intravenous or intraperitoneal injection of 2 mg. of the same material from ten days to nine months previously. The pictures were taken at twenty second intervals beginning with the normal animal (A) photographed before the second injection and ending with the death of the animal (H) which occurred in about two or two and one-half minutes. Such guinea pigs give no cutaneous (tuberculin) reaction with as much as 0.1 mg. of tuberculo-protein.

become evident until large amounts of tubercle bacilli are either injected or disseminated internally after a primary contact with viable tubercle bacilli. The provocative reaction is variable, depending on such factors as are instrumental in anaphylactic shock or reactions. Almost two decades ago, Zinsser<sup>8</sup> reviewed the literature extensively and reported the biologic protein reactions produced by extracts of the tubercle bacillus. He found that the reaction to tuberculin is independent of general anaphylaxis to tuberculo-protein. In its typical and extreme form, hypersensitiveness to tuberculin cannot be induced by dissolved extracts of the tubercle bacillus provided they are filtered through Berkefeld filters to remove formed particles, but it can be induced characteristically by infection with the living bacilli and by treatment with dead organisms (even when boiled). The criticism offered of this work was that it is not clear what organisms were used, that the extracts were relatively crude and that deductions were

as that produced by infection with live tubercle bacilli or by injection of dead bacilli. The most successful methods for preparing and purifying the protein of tuberculin in order to preserve its antigenic capacity were precipitation by means of ammonium sulfate or trichloroacetic acid and mere concentration and washing by means of ultrafiltration. Unfortunately the cutaneous tests were performed in all cases only with large amounts (10 mg., only two pigs having been tested with 0.2 and 0.1 mg. respectively) of tuberculo-protein, and Seibert offered her own criticism of this. Yet according to her as little as 0.000002 mg. of the purified protein will give a good positive reaction in a tuberculous guinea pig. It is noteworthy also that phenol is used as a preservative during the preparation of her tuberculo-protein and that a general lethal dose was found to be only from 12.6 to 17.3 mg. for normal guinea pigs.<sup>11</sup>

It is apparent also that at this time Seibert did not fully understand the significance of the virulence of her strains, since she noted that the guinea pigs "developed varying degrees of skin sensitiveness which roughly paralleled the virulence of the organism used"<sup>12</sup>

Our work was concerned primarily with specific immunity, and yet in view of the fact that allergy, or hypersensitiveness to tuberculoprotein, had been considered previously as an undissociable part of the immune reaction we had to concern ourselves both with the possibility of producing hypersensitiveness to tuberculoprotein and with correlating this with specific immunity. If pure tuberculoprotein would produce a sufficiently high grade hypersensitiveness and if hyper-

of high content, 0.7 mg per cubic centimeter (after longer incubation), was prepared in pure form by precipitation with trichloroacetic acid as well as by aseptic and antiseptic ultrafiltration.<sup>11</sup> In addition the protein was further concentrated by washing and ultrafiltration, so that 1 cc contained as high as 38 mg

*Toxicity of Seitz Filtrate and Purified Tuberculoprotein*—Because there appeared to be evidence that the filtrate from well grown cultures of tubercle bacilli contained a primary toxic material aside from the usual tuberculoprotein,<sup>11</sup> we resorted to ultradialysis through varying grades of cellulose acetate membranes but were unable to demonstrate any increase in toxicity over the original material when measured by tuberculoprotein

Fig 2—Organs of guinea pigs given injections of tuberculoprotein (from Seitz filtrate) in various forms. Note the absence of specific immunity to tuberculosis except when viable avirulent human tubercle bacilli (B) were used prior to virulent infection. A organs of a control animal given a subcutaneous injection of 0.0001 mg of virulent human tubercle bacilli (160) examined two months after infection. B specific immunity shown by the organs of an animal given a subcutaneous injection of 1 mg of viable avirulent human tubercle bacilli one month prior to infection. C organs of an animal treated one month prior to infection with repeated daily intravenous injections of Seitz filtrate (for four days 10 cc containing 0.6 mg of tuberculoprotein per cubic centimeter, a total of 24 mg). D organs of an animal treated one month prior to infection with a single intravenous injection of 5 cc of concentrated Seitz filtrate containing 20 mg of tuberculoprotein per cubic centimeter. E organs of an animal treated one month prior to infection with a single subcutaneous injection of 5 cc of potassium alum treated Seitz filtrate containing 3 mg of tuberculoprotein. F organs of an animal treated one month prior to infection with a single intravenous injection of 100 mg of trichloroacetic acid precipitated tuberculoprotein.

sensitiveness and specific immunity were synonymous, the pure tuberculoprotein should prove valuable for this purpose.

#### EXPERIMENTS

Human tubercle bacilli (virulent) were grown on a nonprotein synthetic medium of simple composition (Wong-Weinzirl<sup>13</sup>), and after from two to six months of incubation at 37 C the bacilli were removed by filtration through a Seitz filter. The tuberculoprotein

content. Our protein concentration in these experiments was approximately thirty times that in the original material, and the partial dialysate was finally concentrated about fifteen times according to the protein content. However, no toxic material other than the tuberculoprotein could be demonstrated in any partial dialysates. Because of the liquid content, the use of plain Seitz filtrates from cultures of tubercle bacilli on the Wong-Weinzirl medium did not prove sufficiently valuable to be continued without modification, but 10 cc (0.6 mg of tuberculoprotein per cubic centimeter) intravenously injected (ear vein) was about all that the guinea pig tolerated and that proved nontoxic to the normal animal. Likewise, one guinea pig given 50 cc

<sup>12</sup> Seibert Florence B and Morley Nelle. The Relationship of the Tuberculin Proteins of Different Acid Fast Bacilli to Sensitization as Indicated by Their Reactivity in Sensitized Animals. *J Immunol* 24: 149 (Feb.) 1933.

(30 mg total) at spaced intervals during twelve hours recovered without appreciable harm, and five guinea pigs each given daily intravenous injections of 10 cc (6 mg total) for four days showed no appreciable toxic symptoms. None of these pigs subsequently had a positive cutaneous reaction to a tuberculin test with purified protein derivative, second strength, or the Seitz filtrate itself diluted 1:10.

The tuberculoprotein in the Seitz filtrate was precipitated with 10 per cent trichloroacetic acid, the precipitate was separated by centrifugation, washed thoroughly with 10 per cent trichloroacetic acid solution and finally washed with ether to remove the acid. The resulting pure tuberculoprotein was suspended in saline solution and injected intravenously (ear vein) into guinea pigs in amounts as high as from 150 to 200 mg in one dose without appreciable toxicity. This tuberculoprotein was tested for tuberculin (skin) potency and found to be equivalent to the original Seitz filtrate and standard purified protein derivative (Parke, Davis & Co.) on the market.

**Toxicity of Concentrated Seitz Filtrates.**—Our first studies with concentrates were made by Seibert's method, using 0.5 per cent phenol, but the injection of

TABLE 1—Primary Intravenous Toxicity for Guinea Pigs of Seitz Filtrates Concentrated by Ultrafiltration

Preservative	Solution Injected,* Cc	Tuberculoprotein		Results
		Mg per Cc	Total	
Merthiolate 1:10,000	3.0	21.5	64.5	Alive
	4.0	27.0	108.4	Recovered
	5.0	32.3	161.5	Recovered
	7.0	21.5	140.5	Recovered
	7.0	21.5	150.5	Died in 24 hrs
	9.0	21.0	193.5	Died in 36 hrs
Aseptic	4.0	27.3	109.2	Alive
	5.0	27.3	136.5	Alive
	6.0	27.3	163.8	Died in 24 hrs
	7.0	27.3	191.1	Recovered
	7.0	27.3	191.1	Died in 24 hrs

\* All the guinea pigs used for tests in these experiments weighed from 500 to 700 Gm. Five cc amounts of 0.1 per cent merthiolate solution in saline solution were without toxicity when given intravenously in control tests on guinea pigs.

the material appeared to produce characteristic reactions to phenol, and we assumed that even washing with weak phenol solutions did not free the material from toxic amounts of phenol. Guinea pigs given intravenous injections died within two days when about 100 mg of tuberculoprotein had been given. Because of the reaction to phenol, we used merthiolate (1:10,000) as an antiseptic preservative<sup>14</sup> and later prepared our concentrates in a sterile closed system, aseptically. The results of illustrative toxicity tests with the aseptically prepared tuberculoprotein and that prepared with merthiolate as a preservative are given in table 1.

The results recorded in table 1 indicate a high grade of tolerance in normal guinea pigs for the tuberculoprotein found in the filtrate from cultures of virulent human tubercle bacilli grown on a nonprotein nutrient medium and given intravenously. Although as much as 150 mg is tolerated by a 500 to 700 Gm guinea pig by careful, slow injection into the ear vein, there are so many other factors aside from the primary toxicity of the protein concerned that it would be only fair to say that this amount is tolerated but may not be the maximum amount tolerated. This is especially so since the trichloroacetic acid precipitated tuberculoprotein

can be given intravenously in amounts as high as 200 mg, after which physical factors complicate the problem. It appears from these experiments that this tuberculoprotein is of low grade toxicity for normal guinea pigs although able to cause a reaction in tuberculous guinea pigs in very high dilution. Attempts to fractionate through dialysing membranes of different density did not prove that the primary toxicity of the protein for normal guinea pigs differed whether obtained in the residue or the dialysate. All the preparations proved of low grade toxicity. It is inferred from this and other experiments that there is no primary highly toxic material (for normal guinea pigs) present in the Seitz filtrate from the growth of virulent (or avirulent) human tubercle bacilli on the nonprotein synthetic medium of Wong and Weinzirl (an ammonium-malate-glycerol-dextrose medium).

**Relation to Anaphylaxis (or Allergy).**—However, when a guinea pig has previously received viable avirulent or virulent mammalian tubercle bacilli in an amount of or exceeding the local tubercle forming dose, tuberculoprotein in sufficient amount (heated or unheated) or very large amounts (about 100 mg) of nonviable (heat-killed) mammalian tubercle bacilli, a second intravenous injection of tuberculoprotein (after two weeks or more) results in acute anaphylactic shock, which is lethal in many cases. A few such results are recorded in table 2.

It is evident from the experiments illustrated in table 2 that viable avirulent and virulent mammalian tubercle bacilli injected into normal guinea pigs in amounts above the threshold of local tubercle formation sensitize such animals so that they give a positive cutaneous reaction to very small amounts of tuberculoprotein. Likewise, only large amounts of heat-killed mammalian tubercle bacilli may sensitize normal pigs so that they react to the ordinary amount of tuberculoprotein used in tests. On the other hand, large amounts of tuberculoprotein (100 mg) given intravenously to normal guinea pigs do not sensitize to a second intracutaneous injection of the same tuberculoprotein even when it is given in amounts as high as 0.1 mg. Yet the viable mammalian bacilli in small amounts, the heat-killed bacilli only in large amounts and the tuberculoprotein in relatively small amounts (about 2 mg) as well as in large amounts (100 mg) sensitize normal guinea pigs to a second provocative anaphylactic reaction to about 1 mg of tuberculoprotein given intravenously.

The foregoing experiments are in accord with the views of Lewis and Seibert that there is a protein in the filtrate of cultures of tubercle bacilli on nonprotein synthetic mediums which sensitizes to and provokes general anaphylaxis. They are also in accord with the work of Zimser, who contended that bacillary extracts in amounts producing hypersensitiveness to general anaphylaxis do not produce cutaneous hypersensitiveness, although our work was carried on with the tuberculoprotein in the filtrates from cultures on nonprotein mediums.

**The Cutaneous Reaction Resulting from Repeated Intracutaneous Injections of Tuberculoprotein (Seitz Filtrates).**—In a large series of guinea pigs given graded amounts (from 1 to 0.00000001 mg) of avirulent human and bovine tubercle bacilli subcutaneously and intracutaneously and including a large number of normal control animals, intracutaneous tests were made at intervals of from one week to one year, the tuberculoprotein in Seitz filtrates (about 0.6 mg of tuberculo-

<sup>14</sup> Jamieson, W. A. and Powell, H. M. Merthiolate as a Preservative for Biological Products. *Am. J. Hyg.* 14: 218 (July) 1931.

protein per cubic centimeter) in dilutions of from 1 1 and 1 10 to 1 10,000 with sterile saline solution being used. The interesting features of this experiment were that, while the guinea pigs that had received the avirulent human or bovine tubercle bacilli subcutaneously or intracutaneously in amounts exceeding 0.0001 mg revealed increasing reactions as the amount of bacilli was increased to 1 mg, a 1 10,000 dilution of the normal Seitz filtrate (0.000005 mg of tuberculoprotein or its equivalent in purified protein derivative) gave a definite positive intracutaneous reaction. On the other hand, repeated intracutaneous injections of the 1 1 dilution (about 0.25 mg per cubic centimeter) into normal guinea pigs never increased the reaction beyond a dilution of 1 10 (about 0.05 mg per cubic centimeter), and even this reaction appeared more or less atypical in its manifestations. It is probably the same reaction Seibert obtained but in lesser degree. Yet one wonders whether the reaction is due to other bacillary materials or extraneous substances when 100 mg of the tuberculoprotein given intravenously results in no sensitization to tuberculoprotein in the skin when reasonable amounts are used for the tests. It may be questioned whether the reaction seen is a true reaction to tuberculin.

*Attempts to Produce Specific Immunity with Tuberculoprotein*—In order to test the ability of various materials (in the Seitz filtrate from the growth of virulent human tubercle bacilli on the Wong-Weinzirl medium) to immunize specifically against infection with highly virulent human tubercle bacilli, various preparations from the Seitz filtrate were injected in various ways into normal guinea pigs. The guinea pigs were then infected subcutaneously with 0.0001 mg of a virulent strain of human tubercle bacilli (strain 160) capable of producing tuberculosis with 0.00000001 mg within two to three months. The substances used for the first injection were the normal Seitz filtrate of varying ages (cultures from two to six months old) up to maximum tolerated amounts totaling 40 cc (on repeated injections after short intervals), with a maximum tuberculoprotein content of from 0.6 to 0.7 mg per cubic centimeter, and to control this, filtrate heated at 100 C for thirty minutes, the purified trichloroacetic acid precipitated tuberculoprotein (100 mg maximum), the filtrate to which sterile potassium alum had been added,<sup>15</sup> injected intravenously and subcutaneously, and concentrated Seitz filtrate (with the equivalent of 100 mg of tuberculoprotein). In control we used guinea pigs that had been immunized with 1 mg of viable avirulent human tubercle bacilli<sup>16</sup> as well as normal guinea pigs. The animals were all tested with tuberculin before infection, and only the guinea pigs that received the viable avirulent human tubercle bacilli gave positive intracutaneous reactions. The animals were killed and examined about two and one-half months after infection with the virulent strain, and in no case, except with the viable avirulent human bacilli, was any retardation of the infection noted. In fact the disease appeared to be slightly aggravated with some of these materials used prior to infection.

Likewise a series of guinea pigs given intracutaneous and subcutaneous injections at weekly intervals (a total of ten injections of normal Seitz filtrate, containing about 0.7 mg per cubic centimeter of tuberculoprotein,

precipitable by trichloroacetic acid) showed a slight aggravation of the tuberculosis in contrast to normal guinea pigs. These injections were discontinued one month prior to infection with a virulent strain of human tubercle bacilli (0.0001 mg.), and the guinea pigs were examined two and one-half months after infection. However, in the guinea pigs given intracutaneous injections there was noted a slight increase in the zone

TABLE 2—General Anaphylaxis Resulting from the Intravenous Injection of Tuberculoprotein in Guinea Pigs Sensitized in Various Ways

Primary Injection	Interval Between 1st and 2d Injection	Cutaneous Reaction to Tuberculoprotein a Few Days Prior to 2d Injection	Provocative Intravenous Injection of Tuberculo protein	Results
5 cc normal Seitz filtrate (2 mg tuberculoprotein)	27 days	0*	1 cc normal Seitz filtrate 0.4 mg tuberculoprotein	Died in 2 minutes
Same as above heated to 100 C for 30 minutes	27 days	0	3 cc normal Seitz filtrate heated to 100 C for 30 minutes 1.2 mg tuberculoprotein	Died in 10 minutes
1 mg avirulent human tubercle bacilli given subcutaneously	2 months	+	3 mg tuberculo protein (Seitz concentrate)	Died over night
1 mg avirulent human tubercle bacilli given subcutaneously	2 months	3	10 mg tuberculo protein (Seitz concentrate)	Marked intoxication recovered
1 mg heat killed avirulent human tubercle bacilli given subcutaneously	2 months	0	10 mg tuberculo protein (Seitz concentrate)	Survived no symptoms
100 mg heat killed avirulent human tubercle bacilli given subcutaneously	2 months	3	10 mg tuberculo protein (Seitz concentrate)	Died in 1 minute
Same as above	2 months	3	Same as above	Marked intoxication survived
2 mg tuberculoprotein (Seitz concentrate)	13 days	0	1 mg tuberculo protein (normal Seitz filtrate)	Died in 2 minutes
Weekly intravenous injection of 13 mg tuberculoprotein	1 week from last injection	0	1 mg tuberculo protein end of 2d week	Died in 2 minutes
Weekly intravenous injection of 13 mg tuberculoprotein	10 days from last injection	0 (to 0.1 mg tuberculo protein)	2 mg tuberculo protein 17 days after 1st injection	Died in 2 minutes
100 mg tuberculoprotein (Seitz concentrate)	6 weeks	0	10 mg tuberculo protein (Seitz concentrate)	Died in 5 minutes

\* The intracutaneous injection of 0.1 cc of 0.005 mg of tuberculoprotein per cubic centimeter was used as a standard cutaneous test in the majority of the experiments since this amount gives a pronounced positive reaction in tuberculous guinea pigs or those given viable avirulent mammalian tubercle bacilli.

+ A 3 reaction is a pronounced reaction of approximately 1.5 cm of erythema with edema.

† Accentuated flare up of cutaneous reaction.

of reaction to this amount of tuberculoprotein, but it was not particularly striking nor did it occur with higher dilutions.

#### SUMMARY AND CONCLUSIONS

1 Specific immunity against infections with virulent human tubercle bacilli could not be produced by Seitz filtrates from cultures of virulent human tubercle bacilli, by highly concentrated (ultradialysis) filtrates or by the precipitated tuberculoprotein or alum-treated filtrates.

2 The highly concentrated filtrates, or precipitated tuberculoprotein, possess no appreciable primary toxicity for normal animals.

3 A primary intravenous injection of large amounts of normal Seitz filtrates, highly concentrated (by ultra-

15 Caulfield A H W Brown M H and Waters E T Concerning the Identity of the Antibody in Experimental Anaphylaxis and That Occurring in Man Naturally or Spontaneously Sensitized J Lab & Clin Med 22 657 (April) 1937 Alum as an Adjuvant in Sensitizing Guinea Pigs to Ragweed Pollen J Allergy 7 451 (July) 1936

16 Footnotes 5 6 and 7

dialysis) filtrates or precipitated tuberculo-protein from these filtrates does not sensitize to a second intracutaneous injection with a fairly large test dose (0.1 mg) of either filtrate or tuberculo-protein. A reaction to tuberculin can be obtained, however, in a tuberculous guinea pig with as little as 0.000005 mg of the same material.

4 A primary intravenous injection of about 2 mg of tuberculo-protein in any of the foregoing forms sensitizes guinea pigs to a lethal intravenous provocative dose (anaphylactically) of as little as about 1 mg of the tuberculo-protein in these forms. This confirms the studies of Zimsser, who worked only with large amounts of bacillary extracts and showed a striking difference between cutaneous and anaphylactic reactions.

5 To produce cutaneous hypersensitiveness to tuberculo-protein requires a small amount of avirulent human tubercle bacilli (a tubercle-forming dose), a large amount of heat-killed tubercle bacilli (around 100 mg) and very small amounts of virulent tubercle bacilli. With the latter, the factors of multiplication and tuberculous involvement complicate the picture.

6 There is a striking quantitative difference between the specific immune and the concomitant allergic or anaphylactic features of tuberculosis which will eventually have to be given independent consideration in the complete evaluation of tuberculosis in man, since one is protective and the other shows a peculiar type of still unsolved intoxication.

## TREATMENT OF MALIGNANT TUMORS OF THE KIDNEY IN CHILDREN

H. DABNEY KERR, M.D.

IOWA CITY

It is now generally recognized that adenocarcinoma of the kidney is one of the most common malignant neoplasms of childhood. Most authors place it next to tumor of the eye in frequency, although at the Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York,<sup>1</sup> it was exceeded in order of occurrence by peripheral sarcoma and bone tumor as well as by ocular neoplasms.

This brief report covers fourteen renal tumors in children seen at the State University of Iowa Hospitals between Jan. 1, 1931, and Jan. 1, 1938. The results in a series of this size are worth recording. While my associates and I make no claim of innovation in either diagnosis or treatment, I am sure that a discussion of both will not be without value.

The pathogenesis of these tumors has been admirably and adequately discussed by Dean and Pack,<sup>2</sup> Hinman and Kutzmann<sup>3</sup> and others. Therefore only a brief review is needed here. Birch-Hirschfeld in 1894 first described as "adenosarcoma" these not infrequent renal tumors of childhood and called the wolffian body the point of origin. In 1899 Wilms wrote his exhaustive monograph on the subject and claimed the origin to be the renal blastema or nephrotome, in this view he has been supported by many authors.

The nephrotome has the power of forming different types of cells but predominantly smooth muscle and tubular elements. However, if the tumor anlage separates earlier it has still greater potentialities for forming diverse types of cells and in such cases one finds tubules, muscle, cartilage and bone. There may also be complete separation of the tumor anlage from the future kidney, so that at operation or autopsy one sees a large Wilms tumor entirely separate from a compressed but otherwise normal kidney on the same side. Case 14 was an example of this. Histologically these tumors are composed of "isolated tubules of high cylindrical or cuboid cells with indistinct lumina surrounded by broad zones of indifferent spindle cells, on which is based the designation of adenosarcoma. Either tubules or spindle cells may be in excess, the tumor approaching embryonal adenosarcoma or sarcoma."<sup>4</sup> Scattered groups of embryonic glomeruli, smooth or striated muscle and occasionally cartilage, fat and myxomatous tissue may be found in the main mass of "indifferent spindle cells." Because of this some authors have preferred to designate these tumors as teratomas or mixed tumors.<sup>4</sup>

### SUMMARY OF CASES

*Age*—Of the series of fourteen patients thirteen were children from 10 months to 5 years old, inclusive, while the fourteenth was 6 years old on admission. The average was 3 1/4 years. These figures agree well with those of other authors.

*Sex*—Although there were nine boys and five girls in the series the experience of other authors<sup>6</sup> indicates that the disease is about equally divided between the two sexes.

*Site*—Reports in the literature<sup>7</sup> show about equal involvement of the two sides, with a small percentage of bilateral tumors. In our series eight tumors were on the right and five on the left, and one was bilateral.

*Symptoms*—All authors have stressed the insidious onset of these tumors and the fact that the first symptom is usually painless enlargement of the abdomen or the finding most frequently accidental, of a large mass in the upper part of the abdomen. This was true in twelve of our fourteen cases. There are occasionally other symptoms but they usually accompany the abdominal enlargement or the mass. These additional symptoms are pain, nausea, vomiting, constipation, diarrhea or general weakness and malaise. It is noteworthy that hematuria occurs infrequently as contrasted with its incidence with renal tumors of adults. Harrah<sup>8</sup> stated that it occurs in from 10 to 25 per cent. Two of our patients had hematuria in addition to the abdominal mass, but none had hematuria alone. Pain was the initial symptom in one case, while general weakness was complained of in the other case in which no mass was seen. Five of the patients had marked prominence of the superficial veins of the abdomen and the lower part of the thorax, indicating pressure on the inferior vena cava or portal vein. In four of these the tumor was on the right side. The duration of symptoms

varied greatly. The longest was two years while the shortest was seven days. The average was 4.4 months.

**Diagnosis**—On the finding of a mass in the upper part of the abdomen, usually painless, in a child 6 years old or younger, a presumptive diagnosis of Wilms tumor can be made. If this is accompanied by displacement and distortion of the renal pelvis and calices on one or both sides, as shown by excretory or retrograde pyelographic study, the diagnosis becomes more certain. Biopsy is not justified. There are, however, other conditions which must be considered. Tumors of the liver, adrenal glands and spleen, hydronephrosis, cysts of the kidney, retroperitoneal or mesenteric nodes and ovarian tumors have been mentioned by various

therefore that for completeness one must include the possibility of lymphangioma when one sees an abdominal mass in a child.

**Metastasis**—In our experience this occurs most frequently to the lungs. Two of our patients had pulmonary involvement when first seen, and in four others it developed during observation. Duration of symptoms and the age of the patient seem to bear no definite relation to the appearance of these metastases. Two patients had metastasis to bone—the first (case 3) eighteen months after admission and the other (case 4) forty-two months after she was first seen.

**Prognosis and Treatment**—All authors admit that the prognosis of Wilms tumor is exceedingly poor

#### Summary of Cases

Case	Age Years	Sex	Admitted	Duration of Symptoms	Side	Pyelo- gram	Urine	Metastases	Irradiation		Survival Mos	Comment
									Primary	Metastases		
1	3½	♂	4/ 2/31	1 mos	L	Unsatisfactory	Trace albumin	Cervix	1 course 1 000 r	1 course 1 000 r	9	Patient too sick to be given adequate treatment dilated superficial veins

writers as possible to confuse with renal tumors. In our experience neuroblastoma of the adrenal glands metastasizes so early to bone that practical differentiation is not difficult. Although it has been stressed by some writers<sup>9</sup> that polycystic kidney is always bilateral and therefore not to be confused with unilateral renal tumor, in one case in which the diagnosis of Wilms tumor was made excision showed one polycystic kidney, while the other kidney showed a normal pyelogram. From this experience, therefore, we feel that polycystic kidney cannot be excluded from consideration simply because of its unilaterality, as has been suggested by some authors. In the other case in which an incorrect diagnosis, of "urogenital ridge" tumor,<sup>10</sup> was made the mass proved to be retroperitoneal lymphangioma. This patient is living, almost six years later, without evident recurrence of the mass, which was incompletely excised. Roentgen irradiation was given postoperatively. We feel

and place the expected mortality at well over 90 per cent. Patients that live five years or more after the beginning of treatment are rare and are worth reporting. A few have survived that long after operation and enough also after irradiation to justify questioning the general statement that one or the other form of therapy alone is hopeless.<sup>11</sup> Operative mortality has been placed by some as high as 40 per cent, with an average of 25 per cent. One of our two patients coming to operation died as a result. For even a fair chance of cure operation must be done early, and because of the insidious onset this is almost never possible.

Most recent authors<sup>12</sup> have advocated the combination of irradiation and surgical measures, giving

roentgen irradiation preoperatively, although some<sup>13</sup> have advocated roentgen therapy alone. I have felt all along that when no metastases were demonstrable irradiation to reduce the size of the tumor followed in about two months by surgical removal was the best procedure. Our experience does not bear out this theoretical conception of proper treatment, since in

Fig 1 (case 4)—A excretory pyelogram showing mass of soft tissue and distortion of the left renal pelvis. B pyelogram showing reduction of the mass of soft tissue and more normal appearance of the area.

case 4 this method was followed and, although the patient lived forty-seven months, she died of generalized metastasis and recurrence in the region of the primary tumor. On the other hand a boy (case 5) admitted at the same time and treated by irradiation in the same way but for whom the parents refused operation is still living fifty-nine months after admission and eighty-three months after the onset of symptoms.<sup>14</sup> In spite of this adverse evidence, I still feel that this result was fortunate rather than logical and agree with those who advocate the combined treatment, rather than with those who suggest that the patients be carried along on irradiation<sup>13</sup> or with others<sup>15</sup> who

Fig 2 (case 5)—A large mass of soft tissue is seen on admission. B disappearance of the mass after irradiation.

have stated that operation alone is more valuable. In our two cases in which operation was done a definitely viable appearing tumor was found, and since these neoplasms always contain more than one type of tissue it is questionable whether the resistant portions, espe-

cially the tubules, can ever be sufficiently influenced to justify their being left in place. My opinion, therefore, based on theoretical considerations and my own experience with patients coming to operation, is that operation should always be used after irradiation when metastases cannot be found. I have found also that one can frequently influence local recurrences by further irradiation. The usual marked reduction in size is due to the response of the sensitive elements. Because individual tumors contain varying proportions of the different cellular elements, too much time should not be allowed to elapse before resorting to surgical measures. At any time beyond three weeks after the cessation of irradiation that the tumor does not continue to shrink, operation should immediately be done. My experience in case 14 illustrates the importance of careful observation following irradiation. The tumor in this case showed only moderate decrease in size following treatment, and the patient was to return in two months for observation. It was eleven weeks before he was seen, and at that time the mass was larger than it had been before treatment. He was operated on and a huge Wilms tumor removed, but he died as a result of the operation. If the tumor

Fig 3 (case 9)—A pulmonary metastases. B disappearance after irradiation. The patient is without demonstrable disease fifty months after admission.

continues to shrink, operation may be deferred up to eight weeks after irradiation. I am not in accord with those<sup>16</sup> who have said that surgical measures should be delayed indefinitely. There is no definite indication that the operation is made more difficult or impossible.<sup>17</sup> Prophylactic irradiation for unproved metastases is not warranted. The average period of survival of our twelve diseased patients was 138 months after admission. The average survival of patients with dilated superficial veins was 54 months, and I feel that this sign indicates an especially poor prognosis.

**Irradiation Technic**—In general, we have used 200 kilovolts and 8 or 20 milliamperes, according to the available machine, Thoraeus filtration (effective wavelength 0.135 angstrom unit and half value layer 1.95 mm of copper) or 0.5 mm of copper (effective wavelength 0.16 angstrom unit half value layer and 0.95 mm of copper) with a distance of 50 cm and anterior and posterior 10 by 15 cm or 15 by 15 cm ports, depending on the size of the mass. A dose of 200 roentgens a day to each port is given till a total dose of from 3,000 to 4,000 roentgens, as measured in air, has been reached. When pressure of work has made the university's three 200 kilovolt machines

<sup>13</sup> Barringer B S. Radiosensitive Kidney Tumors. *J Urol* 38 114 (July) 1937. Portmann.<sup>10</sup>

<sup>14</sup> Since this paper was read this boy has returned showing a local recurrence. This emphasizes the importance of postirradiation removal of the tumor.

<sup>15</sup> Prather G C and Crabtree E G. Kidney Tumors in Children. *J Urol* 25 589 612 (June) 1931. Harrah.<sup>8</sup>

unavailable, we have not hesitated to use 135 kilovolts with filtration by 0.25 mm of copper and have found that regressions of the primary tumor have occurred as soon as when the higher voltage was used. For the two living patients (5 and 9) second courses of treatment were given to the primary area, but this is also true of six of the others. I am inclined to feel that this is worth while, remembering that damage to the skin may result. Pulmonary metastases should be treated, as indicated by case 9, in which three pulmonary nodules have disappeared after irradiation, and case 3, in which they disappeared but the patient succumbed to local recurrence and metastases to the bone. The former patient is still living, without evidence of neoplasm, fifty months after admission and fifty-four months since the onset of symptoms.

#### SUMMARY AND CONCLUSIONS

Fourteen cases of renal neoplasm in children were treated.

Two patients are still alive and without evidence of disease fifty-nine and fifty-two months after admission. One had previously shown pulmonary metastases.

The best treatment for this condition is a full course of roentgen irradiation followed by operation.

Operation should not be deferred beyond the time of continued regression of the tumor.

It is worth while to irradiate metastatic lesions and local recurrences intensively.

#### ABSTRACT OF DISCUSSION

DR MILEY B WESSON, San Francisco. Dr Kerr has carefully culled the literature and has laid before the members all that is known of the subject. Of particular interest is his observation of the behavior of metastasis under irradiation. It is generally agreed that patients in whom irradiation was followed by nephrectomy survived longer than those treated by operation or irradiation alone but the results are nothing to boast about. It is agreed that the time after irradiation for removing a tumor is important. Since no tests except the therapeutic will determine whether the tumor is radiosensitive, all large tumors in both adults and infants should be irradiated before operation. The radiosensitive embryonal Wilms tumors will shrink after comparatively small doses of roentgen rays, but some that have shrunk will regain their original size in six weeks. The rule is to continue irradiation until maximal regression is obtained and then operate. Roentgen therapy is ordinarily considered as only a means of preparation of the tumor for operation or as a palliative measure to hold in check a tumor which cannot be removed. B. S. Barringer has stated that irradiation alone in small doses continued over a long period would seem to be the method of choice in the control of these tumors. One of Kerr's patients treated by irradiation is alive at the end of seven years. Through all the writings of roentgenologists there runs a thread of doubt as to the specific curative value of the roentgen treatment of hypernephroma, but they appear optimistic that when the proper dose is determined the rays will prove to be a specific cure for neuroblastoma. This is interesting in the face of the fact that all patients treated with roentgen rays have died, while Lehman's patient, treated by operation alone, is alive and well after sixteen years. I should like to ask Dr Kerr what his experience has been with this type of tumor in infancy.

DR H. D. KERR, Iowa City. With regard to the treatment of neuroblastoma, my experience is confined to four cases. In none was the condition diagnosed until there was rather widespread metastasis, mainly to the skull and long bones. I did find, however, that these metastases were very radio-sensitive. One patient with involvement of the base of the skull, destruction of the sella turcica, invasion of the orbits and a marked degree of proptosis responded to a relatively

small amount of treatment, so that the mass was reduced, the proptosis entirely disappeared and the sella recalcified. This did not, however, in any way affect the ultimate result. My other patients have responded locally. Dr Wesson's remarks concerning the time of operation are pertinent. It is important to remove these tumors just as soon as they stop regressing, and that requires close observation. Under ordinary circumstances operation should not be delayed longer than six or eight weeks. Barringer feels that irradiation in small amounts continued over a long time may be the best type of treatment, but from my experience I do not feel that this is best. One of my patients had irradiation followed by operation but died forty-seven months after admission from local recurrence and extensive osseous metastases. My next patient is the one who is living eighty-four months after the onset of symptoms. I urged the parents to have the affected kidney removed, but they refused and the patient is living. I feel that this is fortunate rather than logical, because one cannot be certain that any of these tumors will contain only sensitive elements. These tumors are frequently called teratomas because they contain diverse types of cellular elements, and if they contain muscular and tubular elements and cartilage—and one doesn't know that they don't contain them—one cannot expect them to respond entirely to irradiation.

### MANAGEMENT OF 256 CASES OF INFECTION OF THE IMMATURE VAGINA

PRACTICAL DEDUCTIONS, WITH A STUDY  
OF THE USE OF SULFANILAMIDE  
IN TREATMENT

GOODRICH C. SCHAUFFLER, M.D.  
REINHOLD KANZLER, M.D.  
AND  
CAROLINE SCHAUFFLER, B.A.  
PORTLAND, ORE.

Our material comprises a study of 256 patients over a period of nine years in private and clinic practice. An additional group of 261 cases is reported from a national questionnaire relative to the use of sulfanilamide.

#### DIAGNOSTIC METHODS

Smears by Gram stain have been studied in all cases. Occasional disagreements with regard to diagnosis have been finally settled on the basis of cultures. We have learned to rely very strongly on the Douglas chocolate agar method and are at present using it as a routine.

Criteria for cure have remained as formerly outlined—exactness in the extreme. Such a program has, we believe, been instrumental in our satisfactory final figure for cure and our low figure for late recurrence. We prefer to regard recurrence and even possible reinfection as relapse, which of course increases our figure for average time before cure.

#### METHODS OF TREATMENT

*Distention with Silver Nitrate Ointment*—Nineteen cases in which this treatment was used were reported in 1934.<sup>1</sup> The method was found highly satis-

From the Department of Urology, the University of Oregon Medical School.

Read before the Section on Obstetrics and Gynecology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

The names of those who contributed the unpublished data on sulfanilamide appear in table 9. The assistance of Miss Anna Murphy and the Department of Social Service of the Portland Free Dispensary has been invaluable.

<sup>1</sup> Schauflier, G. C., Duke, Ray, Crynes, S. F., and Schauflier, Caroline. Infection of the Immature Vagina. Observations and Results. A Study of 189 Patients. *West J. Surg., Obst. & Gynec.* 42: 669 (Dec) 1934.

factory with regard to final percentage of cures but was comparatively cumbersome and relatively slow in its results. We use it only as a variant to estrogen treatment at the present time.

**Theelin**—Our brief experience with the use of theelin by the hypodermic route was reported<sup>1</sup> in 1934. We treated five patients conscientiously with theelin in ethylene glycol, with unsatisfactory results. Only one patient was definitely and satisfactorily cured.

TABLE 1—Other Methods of Treatment

Treatment with Pyridium

Vaginal amniotin	18	78.3	5	21.7
Oral sulfanilamide†	81	43.1	107	6.0

\* Our series.

† Collected cases.

**Amniotin**—We have treated thirty-one patients<sup>2</sup> by the insertion of amniotin pearls or suppositories into the vagina. Our procedure and dosage are essentially those used by Te Linde.<sup>3</sup>

**Other Methods**—We have used a number of other methods of treatment tentatively, as shown in table 1, which we will not discuss at present.

**Sulfanilamide**—Material for the study with sulfanilamide was compiled by questionnaire and covers 261 cases so treated, only a few of which have been previously reported. These figures are not directly comparable to our own series but they will serve for general comparisons.

#### GENERAL COMPARISONS

The use of the vaginal application of amniotin has given 78.3 per cent cures as opposed to 82.8 per cent for the silver nitrate method and 43.1 per cent for sulfanilamide (table 2). In table 3 it will be noted that elimination of gonococci, relief of symptoms and the time until cure have been substantially less with amniotin than with silver nitrate ointment, as have also the number of visits to the office or clinic (ambulatory patients). Our more recent experience in the amniotin group indicates that increased familiarity with the method is definitely improving our results. It appears that our later cases will give results more nearly approaching those of Te Linde. Our experience with the distention method with silver nitrate ointment, on the other hand, has been sufficient (129 cases), it seems unlikely that we can improve our results in this category. Our report will show that sulfanilamide therapy has been unsatisfactory as used to date and that its use is subject to the

disadvantage of requiring hospitalization for meticulous check-up until all its potentialities are clearly established. We must therefore conclude with the majority of observers that at the present time treatment of this condition by vaginal application of estrogen is the least potentially harmful and the most effective and convenient of all available methods.

#### AMNIOTIN TREATMENT

It should be noted in table 5 that the time elapsed before cure by amniotin as charted is 55.4 days. This is higher than in many series reported. That we have frequently overtreated is indicated by the wide discrepancy between this figure (55.4 days) and the time before clinical evidence of cure—negative smears, 8.3 days, and relief of symptoms, 17.5 days (table 5). Later experience has proved that we might safely have charted a number of our cures sooner, and with less treatments (lower total unitage).

**Amniotin with Adjunct Treatment**—Early in this series nine patients were given supportive treatment with antiseptics on the days when amniotin was not used in the regular routine, that is to say, silver nitrate ointment or pyridium suppositories were used on alternate days after the first week or ten days. More patients (89 per cent) were cured in the mixed treatment group than in the straight amniotin group (70 per cent), but the characteristic vaginal reaction occurred later.

**Comment**—This is a small group of observations but since in the main it bears out the observations of Lewis,<sup>4</sup> Te Linde,<sup>3</sup> Reichert<sup>5</sup> and others it may be considered valid for use in a comparison with a number of different methods used by us. It indicates the following advantages for vaginal estrogen therapy: 1. It is in many cases curative. 2. Elimination of organisms (disinfection) and the disappearance of symptoms are comparatively rapid, i. e., the child is safe for normal contacts and normal living relatively early. 3. The

TABLE 3—Time Factors Under Silver Nitrate, Amniotin and Sulfanilamide

procedure is not difficult. Hospitalization is not necessary. Often it may be taught to parents or guardians and successfully used at home. 4. It is not cumbersome and not expensive. 5. It is apparently not dangerous.

**Disadvantages**—Te Linde's<sup>3</sup> recent extended report is reassuring in relation to possible unfavorable developments due to hormone activity. Our own observations:

4. Lewis, R. M. and Adler, Eleanor L. Gonorrheal Vaginitis: Results of Treatment with Estrogenic Substance. J. A. M. A. 106: 203 (June 13) 1936.  
5. Reichert, J. L., Epstein, J. M., Jung, Ruth and Colwell, Charlotte A. Infection of the Lower Part of the Genital Tract in Girls. Am. J. Dis. Child. 54: 459 (Sept.) 1937.

<sup>2</sup> Amniotin (E. R. Squibb & Sons, New York) was used as an adjunct treatment to sulfanilamide in a few cases not suitable for these records.  
<sup>3</sup> Te Linde, R. W. The Treatment of Gonococcal Vaginitis with the Estrogenic Hormone. J. A. M. A. 110: 1633 (May 14) 1938.

indicate that there is little or no danger. We have noted during five years' use of estrogen therapy that the changes produced in these children, even in those approaching puberty, are transient and apparently rather strictly subject to the influence of the artificially administered hormone. As a matter of fact, the too transient effect of our estrogen medication occasionally defeats the permanent objective of the treatment. Its use over

overcome the natural disadvantage imposed by the crypts and rugae. Furthermore, the mildly irritating and perhaps stimulating effects of certain antiseptics, particularly silver nitrate, may in themselves effect mucosal hypertrophy. Vaginal epithelial hypertrophy contingent on the use of floroquin<sup>6</sup> suppositories has recently been demonstrated by Te Linde. We believe that the advantage of vaginal administration over the hypodermic method is as much contingent on these factors as on a hypothetical local concentration of hormone. We have for years maintained that the creditable results achieved by distention with silver nitrate ointment (tables 2 and 3) are best explained on this basis.

TABLE 5—Time and Dosage Factors in Treatment with Amniotin

Number of Records Clear	Average Days Before Negative Smears	Average Days Before Symptomatic Relief	Average Days Before Cure	Av. Total Dosage Before Cure (International Units)
23	8.5*	17.5*	50.4	37,000

Smallest total dosage			12,000 international units	
Earliest cure			26 days	
Latest cure			111 days	

\* Number of days elapsed before anticipated vaginal wall and pH changes generally coincided with a mean between these two developments.

In our early experience we regarded the potential effect of estrogen on the endocervix with some concern. The possibility that the rudimentary cervical glandular structure which is seen in the specimen illustrated (fig 1) might assume the more potentially infectible adult status seemed feasible. If the endocervix were to be

Fig 1—Below, block showing immature vagina (v) with cervix (c) and endocervix. Note plicae on vaginal cervix and absence of cervical glands also complicated cryptiform vagina. Above endocervix from specimen below. Note high persistence of stratified epithelium and rudimentary nature of glands.

longer periods, in our experience, seems to increase the percentage of permanent cures.

Even in children approaching puberty we have not noted abnormal development of sex characteristics and we have as often noted instances of premature growth of pubic hair, visible growth of labia and breast congestion under other types of treatment. In former communications, before we had used this treatment, we<sup>1</sup> called attention to a "visible thickening and toughening of the skin about the genital area and an early growth of fine hair over the mons with occasional visible development of the labia minora." Our experience in this respect with theelin and amniotin has not gone beyond the condition thus described, except in one instance in which a transient bloody vaginal discharge not accompanied by other demonstrable changes developed in a girl of 4.

At this point it may be permissible to offer a thought in connection with all types of treatment involving distention and manipulation of the immature vagina. It has always been our contention that the infantile vagina may be noted in the specimen illustrated, is anatomically and mechanically a "harbor of infection" (fig 1) and that local therapy by mechanical distention tends to

Fig 2—Nonspecific infection of Bartholin's gland in a 6 weeks old twin seropus exuding from incision.

unfavorably affected in this connection, such effects should certainly be more marked in the older children. However, in this series we have had better results in our older children (90 per cent cures over the age of 7).

6. Floroquin contains diodoquin, lactose, dextrose and boric acid—G. D. Searle & Co., Chicago.  
7. (a) Schauffler, G. C., "Persistent Vaginal Discharge in Infants and in Little Girls," *Am. J. Dis. Child.* 34: 644 (Oct.) 1927. than in our younger children (67 per cent cures under the age of 7). Furthermore, routine careful vaginoscopic study of these cervixes with smears and cultures has not substantiated any such fears. Te Linde reports less favorable results in his older group, which is contrary to our experience.

#### SULFANILAMIDE

Our study of the use of sulfanilamide is based on personal communications and includes only five of our own cases. The material, comprising 261 cases, was

Fig. 3—Nonspecific infection of Bartholin's gland in a 6 weeks old twin before incision

generously offered from eighteen teaching institutions and ten individual observers. Only a few of these cases have been previously reported.<sup>8</sup> All the patients observed showed definitely positive smears and/or cultures for gonorrhea.

The proportion of cures (43.1 per cent) is obviously unsatisfactory, although the time factors are low. The time elapsing before smears are negative is 7.2 days

TABLE 6—Results with Sulfanilamide

Number of Records Clear	Number Cured	Per Cent	Number Not Cured	Per Cent
188	81	43.1	107	56.9 <sup>1</sup>

before there is relief of symptoms 8.7 days and before cure 19.1 days (table 7). Our study at once suggests that the reason for these poor results has been ineffective dosage. Table 8 is of significance in this connection.

Patients in this study were given an average of 0.54 gram per pound of body weight daily over an average total period of thirty days. This is less than one half the dosage per pound of body weight used for children (1.32 grains<sup>9</sup>) under treatment for serious infections. Blood concentrations when they have been recorded in this study have been low, as would be expected considering the per pound dosages. With very few exceptions they have remained well below 3 mg per hundred

<sup>8</sup> Abbreviated reports of thirty of these cases have been previously published (Hoffman, Carey and Hageman). Reports of forty-two others are awaiting publication (Holmes).

<sup>9</sup> This was the average daily dosage per pound to seventy-nine children treated by nine observers for conditions other than vaginitis. Tremendously larger individual doses were used in many cases without apparent harm.

cubic centimeters of blood. It is generally conceded that children eliminate sulfanilamide more rapidly and more efficiently than do adults. Therefore, in order to maintain an effective blood concentration, larger per pound dosages can and must be used. This being the case, it is interesting that sulfanilamide has been used more sparingly and apparently with greater concern in these patients than in patients debilitated by serious infections. No alarming reactions have been noted.

A further analysis of dosage factors reveals, interestingly enough, that inadequate dosage is apparently not the only important factor in poor results. For example, patients receiving larger doses (either total or per pound of body weight) have apparently not produced more or earlier cures than those less thoroughly treated. Furthermore, there appears to be no clear

TABLE 7—Time Factors with Sulfanilamide

Average Days Before Smears and Cultures Are Negative	Average Days Before Relief of Symptoms	Average Days Before Cure
7.2	8.7	19.1

relationship between the total time under treatment and the number of cures, and no more cures appear to result from prolonged treatment even under the larger doses.<sup>10</sup> The confusion in this series may be contingent on such consistent, ineffective doses or it may all point, by a process of elimination, to the fact that the administration of the drug has not been timed or dosed to maintain an effective blood concentration at all times. Increasing evidence indicates that constant administration of the drug, day and night, during the period of treatment is important and has not been emphasized in most of these cases. Scott and Winters, who maintained a constant blood concentration of from 2.3 to 5.2 mg per hundred cubic centimeters by medication every three to four hours, day and night, report five cures in five cases.

Fig. 4—Foreign bodies removed from vaginas of children of (A) 3 years (B) 6 years and (C) 5 years. The large safety pin A had been present in the vagina of the 3-year-old child for at least six weeks. The child had been examined and treated by two other physicians.

treated. It is now apparent that hospitalization is necessary to the effective conduct of this type of treatment. Continuous medication, rest, blood studies and careful observation will remain essential, at least until limits

<sup>10</sup> Hoffman's patients appear to be the only group who profited by repeated and prolonged medication. Others suggest a tolerance developed to the drug after a given period of administration. Local application by the suppositories (Holmes) and hypodermic administration (prontosil the disodium salt of 4-sulfamido-phenyl-2-azo-7-acetyl-amino-1-hydroxynaphthalene-3,6-disulfonic acid) has not been thought helpful.

of safety and effectiveness can be more clearly delineated. Since from all other angles institutionalization is definitely contraindicated, this must be considered a disadvantage.

acid reaction on the action of sulfanilamide should be considered. The notable effectiveness of sulfanilamide in gonorrheal ophthalmia is of interest in this connection, the reaction of the eye being mildly alkaline.

Note—Per cent scores calculated from 1 to 100 according to preceding footnotes

The opinions of all observers have been analyzed in table 9. The total consensus is only 55.1 per cent favorable. It is regarded as inferior to other methods by the majority, and nearly half will discontinue its use in this connection. Low dosage and failure to maintain the blood concentration may be responsible. The possibility of a connection between the desired acid reaction of the vagina and the unfavorable effect of an

## SOME GENERAL CONSIDERATIONS

**Endocervix.**—We agree with Te Linde that infection of the endocervix is seldom a factor of importance and have been disputing the matter since 1927. An early misconception was created by misquotations from Hess, who examined four infected children post mortem and determined that in every case there was infection of the cervix which, however, did not extend beyond

or in some cases even to the external os. Hess has been repeatedly and mistakenly quoted as having demonstrated true endocervical infection. As far as we can determine, it has never been demonstrated in the smaller children. To be sure, positive smears from the cervix may frequently be contaminated by material from the region of the external os, but the cervix itself is seldom if ever infected—in fact scarcely infectible except in older girls—because of its negligible gland structure (fig 1). The vaginal cervix, on the other hand, is in many instances more deeply rugose than the vaginal wall and its involvement is quite another matter, a definite entity, and fortunately amenable to measures that affect the vaginal wall in general.

**Proctitis**—We believe that proctitis accompanying gonorrheal vaginitis is not infrequent and that by attention to this possibility we have cut down our incidence of recurrent vaginitis. Smears and cultures are seldom helpful, but we have noted, accompanying frank vaginal gonorrhea, a definite purulent discharge from the rectum, associated occasionally with bleeding always with painful defecation. Treatment by nightly rectal instillations of a 1:500 water solution of merthiolate and more recently with an oily solution<sup>11</sup> of azo-chloranil has been apparently helpful.

**Bartholin's Gland**—Our histologic study of Bartholin's gland areas post mortem has revealed underdeveloped rudimentary gland structures,<sup>12</sup> and clinical experience indicates rare involvement. We have seen, however, two instances of undoubted Bartholin's infection—both nonspecific. Figures 2 and 3 show the right Bartholin's area in a twin girl aged 6 weeks weighing 6½ pounds (2,948 Gm.), who had no vaginitis. Thin seropus drained after incision, and healing was complete.

**Urethra**—We have taken urethral smears and cultures only in stubborn cases. We have never noted a positive result in a case in which there was not also a frank vaginitis. It appears that infection seldom if ever occurs in the urethra as a primary or persistent process. We have examined the periurethral glands in postmortem specimens from uninfected infants. They are definitely present and in some instances quite well developed and intricate, not being restricted to the glands of Skene.

**Trichomonas Vaginalis**—Moist vaginal secretions have been examined for trichomonads in practically every case showing a discharge not demonstrably gonorrheal. We have found active trichomonads in only one instance, this patient being an older girl of about 13. We believe that the trichomonad is a rare, almost negligible, factor in this connection.

**Foreign Bodies**—We have removed three foreign bodies—two safety pins and a red crayon. The metallic objects both caused a bloody discharge, all three objects caused painful urination. Two patients were treated by physicians for suspected gonorrhea, one for four weeks, before we removed the foreign body.

**Pinworms**—Pinworms were found in four patients, three with nonspecific and one with gonorrheal vaginitis. In one patient a worm was detected invading the vagina, in another a worm was detected within the vagina.

**Pelvic Infection**—This has been noted definitely in four instances. A diagnosis of a ruptured appendix was missed by the surgeons because of a past history of vaginal discharge.

## SUMMARY

1 A critical evaluation of our experience with distention with silver nitrate ointment in ninety nine cases, amniotin by vaginal application in thirty one case, pyridium suppositories in nineteen cases and various other methods in smaller series leads to the conclusion that amniotin by vaginal application is the most satisfactory method of management we have used to date.

2 This study includes 261 cases in which sulfanilamide was used orally. Only a few of these cases have been reported elsewhere. The results and opinions indicate that the method is unsatisfactory as used to date. The reason may be inadequate or inconstant administration of the drug. The desired low  $pH$  of the vagina may be important in relation to the ineffectiveness of sulfanilamide. Meticulous care during treatment requires hospitalization—a disadvantage. The method is used thus far apparently does not compare favorably with other available methods.

3 Evidence from a rather painstaking study indicates that the endocervix is seldom an important factor in relation to these infections—practically never so in younger children.

## ABSTRACT OF DISCUSSION

DR C F FLUHMANN, San Francisco. In discussing this paper it is important to remember that the authors have made a study of the problem of vulvovaginitis in children for many years and their opinions therefore deserve all the more consideration. In the Stanford clinic my associates and I have had too limited experience with children to warrant a statistical study of results, but our general impression coincides with that of the authors. The two methods of treating this disease which are now exciting major interest are the local application of estrogenic substances and the administration of sulfanilamide. The authors have given figures comparing the efficacy of the two procedures and it appears that estrogenic treatment is the method of choice. A fundamental consideration in the evaluation of new therapeutic measures must always be that of possible harmful complications. It is known that sulfanilamide must be handled with great care. The patient must always be under close supervision. Blood counts must be made frequently, and in spite of all precautions a number of unfortunate adverse effects make their appearance. With estrogenic therapy it is not known yet whether really serious consequences may occur. Some students of the problem have drawn attention to an abnormal development of the breast and pelvic organs, and it has even been suggested that this treatment may lead to the development of cancer. Recently there have been reports of overgrowth of the accessory genital organs of boys treated with the chorionic hormone. It is conceivable that in time complications also may be observed to follow hormone therapy of vaginitis in young girls. However, our present knowledge of the action of estrogenic substances and its conservative interpretation renders the probability of any real harm remote. The suggestion of cancer in children treated with therapeutic doses, I feel, merely represents a phobia. The development of the accessory genital organs and the breasts should not lead to permanent damage. I feel certain that estrogenic therapy conducted with due care and with therapeutic doses for limited periods is safe, but there may be real danger in prolonged treatment.

DR H CIOSE HESSELTINE, Chicago. I do not mean to discourage unnecessarily the use of sulfanilamide in treatment. However, I should like to ask whether the authors have demonstrated the presence of sulfanilamide in the vagina of the child, and if so in what concentration it was found. One reason for this question is that in the paper to follow it is noted that sulfanilamide has not been found in probable bactericidal concentration in the adult vagina. If it appears in

11 One to twenty dilution in oil of triacetin (1:500) solution

a pronounced concentration, that would explain its action but if it does not appear in bactericidal or bacteriostatic concentrations an explanation is needed for its accredited therapeutic action

DR GOODRICH C SCHLAUFLER Portland Ore In relation to Dr Hesseltine's question, I must answer by inference. I have it in mind that determinations have been made of the concentration of sulfanilamide in the vagina of these treated patients, and my impression is that the concentration is consistently lower than the concentration in the blood of the same patient. This is my inference, and I think the point is important. It is interesting that sulfanilamide has been used locally in the vagina by J W Holmes at the Philadelphia General Hospital in five cases, and in four cases a severe bloody discharge occurred with definitely unpleasant reactions and the treatment had to be discontinued. I am deeply interested in Dr Lohmann's comments. It occurs to me that Dr Fluhmann, before the estrogenic treatment was adopted in this connection, made observations in relation to leukocytic infiltration in the adnexal tissues in patients under treatment with estrogenic substances. His study of the possibility of a favorable reaction to the use of estrogenic substances in connection with genital infections was one of the earliest contributions to this problem.

## THE STUDY AND SUPERINTENDENCE OF HOSPITAL PROCEDURES

SUGGESTING THE CREATION OF A SPECIAL COMMITTEE  
OF THE MEDICAL STAFF AND ADMINISTRATIVE  
OFFICERS FOR THE PURPOSE

J J GOLUB, MD  
Director Hospital for Joint Diseases  
NEW YORK

The medical staff and administrative officers of a hospital must concern themselves alike with its interior composition and outer conditions. A hospital, like a patient, has an inside which must be studied with the purpose of altering and discovering theory and practice of its healthy service and development. In a healthy smoothly functioning hospital

- 1 Physicians and surgeons have every facility and encouragement to diagnose and treat disease
- 2 Patients can rest in comfort and as individuals be understood and reasonably satisfied
- 3 Professional and administrative methods and procedures can be continuously watched over, controlled and qualitatively analyzed
- 4 Patients can be instructed in the simple practices of hygiene and the special measures to be carried out at home such as dieting, exercise and prevention of disease
- 5 The condition of discharged patients can be observed by periodic follow-up service
- 6 Physicians and nurses can learn and teach
- 7 Medical students and student nurses can learn
- 8 Clinical and laboratory research work can be pursued

In this paper I wish to discuss the third point in the list, namely the creation of conditions within the hospital which would permit continuous study and constant control of professional and administrative practices and procedures. The purpose, however, is not to minimize the progress made by physicians and hospitals in the many effective and well directed procedures but to point out the significance and size of the unfinished task.

If it is true that 'nothing is so stale as yesterday's newspaper,' it is not less true that, in the hospital today's practice may be obsolete tomorrow. Nothing is so ineffectual and wasteful as "routine" of long standing the efficacy of which no one questions or

undertakes to check periodically. Repetition of motions and steps which have been standardized without constantly checking their effectiveness and without comparison with the improved methods that the ever changing phases of hospital and medical care bring in, is good neither for the patient nor for the hospital. Such heedlessness rests on precedent, habit and laziness.

When the patient arrives, the machinery of the hospital is set in motion—orders and procedures are set in motion and focused on him as if he were the only patient to be considered. Between the time of the patient's admission and his discharge from the hospital, about sixteen major administrative and professional departments of the hospital serve him directly and indirectly. The extent of the service the average patient requires can be better understood by recalling the fact that general hospitals have about one and a half to two and a half employees for every occupied bed. This, of itself, requires repeated examination of the usefulness of hospital procedures, jointly and severally, as wholes and in their constituent parts. It should enhance the comfort of the patient and keep standards of service and economy high. It should eliminate techniques and hazards which may have ill effects on patients, and it should lessen litigation as a result of malpractice claims. To accomplish this calls for special attention to

(a) The control and supervision of all matters pertaining to administrative and professional practices and procedures

(b) The observation and study of existing practices and procedures, by making repeated qualitative analyses of their merits, efficacy and hazards. This would include continuous research and experiment within the hospital

(c) The observation and study of new practices and procedures as developed elsewhere, with a view to their introduction into the hospital

(d) Recommendation to the hospital authorities of modification, substitution and elimination of practices and procedures as indicated by controlled observation and study, and by current scientific advances

But who shall pay this attention, the administrative or the medical staff?

It would be difficult to designate certain practices and procedures as belonging solely to one group or another or to one of the usual departmental committees of the hospital. It is not difficult, however, to see that they belong to the hospital as a whole and are the responsibility of the hospital, that is, the joint responsibility of the two staffs. Both staffs, it follows, should find a workable way of assuming this responsibility.

Here one way is suggested. The medical staff (say through its medical board) should appoint a committee to be known as the Committee on Hospital Practices and Procedures. This committee should be functional in character in contradistinction to a departmental committee, which confines its activities to one of the usual hospital departments. The committee should, as far as possible, consist of the director of laboratories, the roentgenologist, the anesthetist, the physical therapist, the transfusionist, a surgeon, a physician and the executive director (in a large hospital one of his assistants). When a matter relating to a particular department is under consideration, the committee would invite a representative of the department to participate in its deliberations. Thus it might call in, as the occasion required, the supervisor of nurses, the supervisor of the surgical operating suite, the nurse-anesthetist, the senior house staff member, the dietitian,

the supervisor of social service, the supervisor of the outpatient department and other department heads

In a large hospital the committee might find it advisable to engage a full-time research assistant—one endowed with curiosity as well as with research qualities. He would devote himself to the activities outlined for the committee.

A complete discussion of all hospital practices and procedures that would come continuously under the watchful eye of this committee could not be given within the limits of this paper. The few discussed represent a fair sample of a much longer list. They are different enough and numerous enough to show how needful is the critical examination of hospital procedures, especially those likely to be outmoded and become inconsistent with high standards of service for the sick.

The eight to be discussed are

- 1 Preoperative and anesthesia precautions
- 2 Surgical operating rooms—policies and technics
- 3 Postoperative precautions and infections
- 4 Cross infection in occupied wards and control of contagious disease
- 5 Blood transfusions and intravenous infusions
- 6 Patients without visitors
- 7 Hospital admissions
- 8 The fate of the discharged patient

#### PREOPERATIVE AND ANESTHESIA PRECAUTIONS

The committee would undertake a critical study of what is done with the patient prior to operation with the purpose of establishing well grounded rules of procedure. For example, it would establish a policy regarding surgery during an influenza epidemic and on very hot and humid days, and regarding what person should be empowered to cancel scheduled operations on such days.

It would study both the various standing preoperative orders and those given by the surgeon, and evaluate them. It would determine the efficacy of blood agglutination tests before tonsillectomy, whether children shall receive the usual preoperative dose of morphine, whether, when and where the surgical area shall be shaved, cleansed and painted with iodine—the night before or immediately before operation in the patient's bed or in the operating room. Who shall check whether the patient signed the usual permission slip consenting to submit to surgery? Who shall control the unusual and often unjustifiably long time patients are held on the operating room floor before operation and how shall he control it? Who shall mark the exact part where the operation is to be performed to avoid operation on the wrong part? Whose duty shall it be to identify the patient—the surgeon's, the anesthetist's or the nurse's—one or all—before anesthesia is administered so as to make sure that the right patient will undergo the indicated operation? Of what shall the identification consist?

#### SURGICAL OPERATING ROOM POLICIES AND TECHNIQS

Rules and regulations governing operating room policies and technics also require periodic revision. Ways should be designated of bringing them regularly to the attention of the surgical staff and the personnel of the operating suite. In formulating them the following questions among many others should be considered.

In scheduling patients for operation, what are the roles respectively of the operating room supervisor, the house surgeon, the anesthetist and the admitting officer?

How shall constant asepsis be maintained?

Who is responsible for insuring the complete sterilization of all materials?

Shall the laboratory or the supervisor of nurse be held responsible for the regularity of periodic bacteriologic examinations of sterile materials, water and surgeon's hands? How often shall such examinations be made and by what criteria shall the sterility be measured?

What shall the practice be with regard to the "scrubbing" of hands? Shall surgeons and nurses be required to "rescrub" their hands when going from one operation to another or merely change their gloves and gowns?

Who is responsible—the surgeon or the nurse—for the accurate count of sponges and how shall it be controlled?

Who shall instruct the house staff and nurses in the use of the resuscitation apparatus?

Who shall check the ever readiness of emergency trays for the usual operating room emergencies?

What shall be done to eliminate the dangers of electrical and gas ignition of anesthetics?

What shall the safeguards be to avoid the breaking of needles in spinal and other injections?

#### POSTOPERATIVE PRECAUTIONS AND INFECTIONS

The practices and procedures discussed under the title of postoperative precautions and infections have two aspects.

One is the general postoperative care which begins the instant the surgeon completes his work. Regarding this the questions are: Who shall issue postoperative orders, what shall they be and to whom shall they be issued? Who shall accompany the patient from the operating room to his bed—the house surgeon, the anesthetist, the orderly or the nurse? Who shall check the condition of the room to which the patient is being returned from the standpoint of drafts, heat, quiet and watching until the patient has completely reacted to the anesthetic?

The other envisages procedures of precaution against postoperative infections of the surgical or obstetric area. The questions here are: What are the practices in dressing of wounds? Is strict asepsis observed in all the steps taken? How and when are patients catheterized? What restrictions govern prepartum examinations so as to prevent postpartum infections? What are the practices and procedures with relation to the care of the newborn? What is the policy concerning medical and surgical patients occupying beds in one ward or room?

#### CROSS INFECTION IN OCCUPIED WARDS AND CONTROL OF CONTAGIOUS DISEASE

The study of the field of cross infection in occupied wards and the control of contagious disease raises the following questions. What is the hospital policy concerning admissible and inadmissible diseases? For example, are patients with erysipels or active gonorrheal urethritis or pulmonary tuberculosis to be permitted to occupy beds in rooms or wards occupied by other patients? What are the known theories and facts concerning the transmission of disease? Which diseases are transmitted through air, droplets, water and food? Which diseases are transmitted through direct contact? Is there a relationship between the area and cubic content of a ward or room and the number of occupied beds? Does crowding influence cross infection, and how? What knowledge and experience are

available regarding the relationship of ventilation, filtered and washed air and air conditioning to cross infection?

#### BLOOD TRANSFUSIONS AND INTRAVENOUS INFUSIONS

Some of the questions to be considered under the heading of blood transfusions and intravenous infusions are

In busy hospitals where many transfusions follow one another, what shall be the practice in identifying the right donor for the right patient after both have been typed so as to avoid the fatal error of transfusing blood from one blood-type donor to another blood-type patient? What shall be the safeguards against the transfusion of blood from donors infected with syphilis or malaria? Who shall be responsible for this vital check—the transfusionist, the hematologist or the operating room nurse? What are the causes of chill and fever reactions after transfusion or any intravenous infusion—the rubber tubing, the temperature of the blood or solution, the speed of the flow, the volume, the degree of concentration, the age of the solution, the faulty distillation of the water or what?

#### PATIENTS WITHOUT VISITORS

Medical social service supplements medical care. Its work should aim to make the patients in poor circumstances more comfortable mentally at ease, physically stronger, and economically easier either directly or through other relief agencies. Social service should enable the hospital better to understand the patient and the patient better to understand his medical and social problems, and thus to cooperate more willingly in their solution. Yet often when much or all of this is done the patient without visitors is forgotten. Who is he and why is he friendless? Where is he going when he leaves the hospital? Social service may evade the function of becoming a collecting or rate adjusting agency of the hospital but many of the practices and procedures which it does accept require study and supervision. It is legitimate social service to befriend lonely patients. There should be no clash between the emerging profession of social service and humane acts of this sort which are not usually described in the textbooks dealing with that discipline. They have been known even to hasten the recovery of patients.

#### HOSPITAL ADMISSIONS

The "routine" of hospital admissions rarely includes consideration of the mental attitude of the patient who has been taken from the familiarity of home and family to the strange atmosphere and strange personnel of the hospital. Usually the only person he knows is his physician, who visits him once or twice a day or once every other day. During all other hours the patient is served and watched by a nurse who is a stranger to him and whose time and attention may have to be divided with one or more other patients.

It is not sufficient to try to cure physical disease. The hospital must guard against conditions during such treatment which hurt the mind of the patient. The patient's reaction to unfamiliar hospital sights and people, talk or silence, fears and complacency may not be ignored. This is a task in our present day complex hospital setting that requires at least no less thought, no less planning and no less expenditure than does, say, the hospital's bookkeeping department.

Shall not the ways and practices of the admitting officer and of the nurses and house staff members as

they relate to newly admitted patients be examined? What can be done to insure the patient's mental comfort and elimination of anxiety which often eclipse his physical improvement? To find suitable answers to these questions would be an important assignment of the committee.

#### THE FATE OF THE DISCHARGED PATIENT

It is easy to agree with Lincoln Steffens "that nothing is done finally and right" and "that nothing is known positively and completely." Many timely and needed changes are yet to be made in hospital administration, hospital service, and hospital planning and construction. These changes are possible because it is hard to recall another period when public interest in the hospital was greater than it is today. It is also hard to recall another period when the hospital as an integral institution of the community was more acceptable to the people, its services more essential to their well being and its progress of greater concern. To retain these qualities the hospital must increasingly realize that its responsibility to the patient discharged as "improved" and especially to the patient discharged as "unimproved" does not end when the patient leaves its doors. In this connection the committee should seek answers to the questions: What are the instructions issued to patients on leaving the hospital? To what sort of homes are they returning? What is the responsibility of the hospital in providing facilities for convalescent care? What are the aims of "follow-up" service? How is it conducted and what efforts are made to have the patient return for "check-up"? In a word, what hospital practice should be set in motion to insure lasting cure and to find a way of improving the condition of the patient discharged as "unimproved"?

#### THE HOSPITAL'S RESPONSIBILITY

It might be suggested that all practices and procedures are the responsibility of the respective committees of the medical staff already formed to deal with them, that they are the responsibility of the heads of the clinical divisions or of the hospital administrative department heads. Preoperative and postoperative precautions are the business of the surgeon, the anesthetist and the Committee on the Surgical Operating Room and Anesthesia. Surgical operating room policies and techniques are the responsibility of the operating room nurse and surgeon and the same committee, blood transfusions of the transfusionists and a corresponding committee, and so on. But there usually is more than one surgeon and often more than one transfusionist. Whose duty is it to handle cross infection hazards? Who shall investigate sudden deaths in the operating room or in the ward and what are the lessons that could be learned from such investigations? And who shall observe, seek explanation and indicate measures of control over the frequency of orders for x-ray and laboratory examinations which are unusually high for ward patients as compared with private patients with the same conditions? These and many other activities that make up today's highly complex hospital do not belong exclusively to one controlling source. Many practices and procedures involve more than one hospital service and more than one of the regular medical staff committees. There is overlapping and much divided responsibility. These difficulties indicate the value of one central study and advisory group to evaluate, discriminate, disseminate and supervise practices and pro-

cedures of the scores of professional and administrative workers who directly and indirectly serve patients.

There is much to appreciate in the modern American hospital. Its evolution from the old types of buildings to new functional interiors, complete in equipment, that are also beautiful and brightly furnished and easy to operate is a matter of pride. Should not hospital organization seek parallel improvement in service, directed toward the welfare, comfort and cure of the patient? This is what a joint committee of representatives of the medical staff and administration, devoting itself to matters pertaining to professional and administrative practices and procedures could seek and find. The medical board of the hospital would review its conclusions and recommendations and see that those accepted and approved become (after ratification by the board of trustees of the hospital) the practices and procedures of the hospital until again changed or eliminated.

1919 Madison Avenue

## RELATIONSHIP BETWEEN NICOTINIC ACID AND A CODEHYDROGENASE (COZYMASE)

IN BLOOD OF PELLAGRINS AND NORMAL PERSONS

RICHARD W. VILTER, M.D.

SUE POTTER VILTER, M.A.

AND

TOM D. SPIES, M.D.

CINCINNATI

Growth factor V for bacilli of the influenza group has recently been identified as a codehydrogenase (cozymase or coferment).<sup>1</sup> The Lwoffs<sup>2a</sup> have shown that bacilli of this group which require the factor cannot synthesize it from its components, nicotinic acid amide, adenylic acid, ribose and phosphoric acid. Because of the well known importance of nicotinic acid and nicotinic acid amide in the treatment of human pellagra,<sup>2</sup> it seemed important to investigate the content of factor V in the blood of pellagrins for the cozymase of von Euler<sup>3</sup> and the coferment of Warburg<sup>4</sup> are the only two known active biologic substances in which nicotinic acid amide is found. We have shown that *B. influenzae* can be used to measure accurately the cozymase content of the blood in normal persons and in pellagrins. Furthermore, prolonged treatment of several hundred pellagrins with nicotinic acid has shown that in most cases there is an immediate increase in sense of well-being and vigor and a prompt relief of

the symptoms of acute pellagra.<sup>5</sup> In a rather high percentage of the pellagrins, however, it is necessary to increase the dosage from time to time in order to keep them free from recurrences. In two instances as much as 1,000 mg. of nicotinic acid a day was required.<sup>6</sup>

Manifestations of vitamin B<sub>1</sub> deficiency often appear in the endemic pellagrins who subsists on his usual diet and ingests large amounts of nicotinic acid each day.<sup>7</sup> This vitamin B<sub>1</sub> deficiency can be prevented, at least for a considerable period of time, by the addition of 10 mg. of crystalline vitamin B<sub>1</sub> to this diet. Likewise, while pellagrins show definite improvement following the administration of nicotinic acid and vitamin B<sub>1</sub>, if the patient remains on a deficient diet certain symptoms will again develop in some of the patients. This suggests that even though two essential substances, nicotinic acid and vitamin B<sub>1</sub>, are supplied, the diet usually ingested by these patients must be deficient in still another substance or substances.

During the past five years we have attempted to determine the role of riboflavin in human nutrition, but we were not able to demonstrate a clearcut usefulness for this substance as a therapeutic agent in the treatment of deficiency states in human beings. Therefore four endemic pellagrins were selected for preliminary study in Birmingham, Ala. These pellagrins were maintained on a pellagra-producing diet and were treated by administering from 100 to 400 mg. of synthetic nicotinic acid and 10 mg. of synthetic vitamin B<sub>1</sub> each day as supplements to the diet. Within twenty-four to forty-eight hours after the administration of these substances was begun, great improvement in the patients occurred. They continued to eat the pellagra-producing diet and supplements of nicotinic acid and vitamin B<sub>1</sub> were given each day, but within one to two months the patients began to lose appetite and weight, and very mild dermatitis appeared. Past experience had shown that by administering still larger amounts of nicotinic acid another period of improvement could be induced, but we decided to keep the intake of food, nicotinic acid and vitamin B<sub>1</sub> constant. The general clinical condition of these patients remained essentially the same during the subsequent ten months. In order to rule out the effect of any psychotherapy, we gave, in addition to nicotinic acid and vitamin B<sub>1</sub>, sodium bicarbonate and acetylsalicylic acid to each patient for three days. No subjective or objective improvement occurred. Since some of the patients experienced a recurrence of certain symptoms even though nicotinic acid and vitamin B<sub>1</sub> were given, and in view of our belief that riboflavin is involved in the metabolism of nicotinic acid or substances acting similarly, either as a complementary therapeutic agent to form a conjugate within the body or as a constituent of the diet essential in itself, we administered 50 mg. of riboflavin to each patient. On the second day an additional 50 mg. was given. Within forty-eight hours each patient showed improvement in sense of well being, improvement in the cutaneous lesions (the dermatitis in these four patients did not go through a period of erythematous change and, in general, appeared much more chronic than the characteristic pellagrous dermatitis) and increased vigor. Thus, we feel supports our

belief that riboflavin does have some function as a therapeutic agent in the treatment of certain deficiency states in human beings<sup>6a</sup>

These observations suggest that nicotinic acid is probably not used as such by the body but more likely is used as a component of some enzyme system, and that riboflavin is also beneficial to certain pellagrins in

\* The extent of growth was interpreted as follows: ++++ = very heavy; +++ = heavy; ++ = moderately dense; + = light; ± = just perceptible; — = no growth

relapse. The present report is concerned with the therapeutic effect of nicotinic acid as demonstrated by an increase in the quantity of these active enzymes in the blood. The growth of influenza bacilli in serial dilutions of human blood has been used as a measure of the amount of this specific growth factor present in blood.

#### METHOD

Five cultures of *Bacillus influenzae* and *B. parainfluenzae* were obtained, carried on chocolate agar slants and studied in broth subcultures. The broth was prepared with 2 per cent Difco proteose-peptone, 0.6 per cent salt and 2 per cent human blood. This medium, pH 7.6, was heated to 95 C and filtered. Then a portion was sterilized by filtration through a Seitz filter and another portion was autoclaved. As was expected, the portion of autoclaved medium was found not to support growth of those members of the influenza group studied, since cozymase, factor V, is destroyed by autoclaving. The unautoclaved medium, in contrast, provided luxuriant growth of these organisms, as has been shown previously by Davis<sup>8</sup> and by Thjotta and Avery.<sup>9</sup>

The procedure was as follows: One cc of venous blood was added to 19 cc of sterile distilled water and heated in a water bath to 85 C until the solution became brown. The solution was cooled and, after the addition of one or two drops of sterile tenth normal hydrochloric acid, was centrifuged. The supernatant fluid was then added to tubes of autoclaved peptone broth so that the final dilutions of blood added to the prepared medium represented volume ratios of 1 1,000, 1 2,000, 1 4,000, 1 8,000 and 1 12,000. The blood was heated to 85 C so that the proteins could be centrifuged out and the labile inhibitory substance in the serum described by Rivers and Leuschner<sup>10</sup> would be partially or totally destroyed.

#### SELECTION OF CASES

A series of blood studies were made on four healthy, well nourished persons and three patients with mild attacks of pellagra who were admitted to the Cincinnati

General Hospital. Of the pellagrins, H J entered in relapse and, after recovery, was maintained on a pellagra-producing diet for two months (Dr W B Bean and Miss Jean Grant contributed in the dietary control of this patient and in the therapy of the other pellagrins). F H and W S entered with mild lesions which healed after rest in bed, although the patients were maintained on a pellagra-producing diet.<sup>11</sup>

#### OBSERVATIONS

The blood of normal persons was found to support growth up to dilutions in peptone of 1 12,000 when the procedure outlined was used with loop transfers of a twelve to eighteen hour culture of *B. influenzae* as the inoculum (table 1). In contrast, the blood of the three pellagrins supported growth poorly and only in the lower blood dilutions, i. e. 1 2,000 (table 2). They contained therefore, much less factor V than normal. The blood of these pellagrins, however, after nicotinic acid therapy, supported the growth of *B. influenzae* almost as well as the blood of the normal persons studied. Patient H J was maintained six days on the pellagra-producing diet before the administration of nicotinic acid. Then, while still on this diet, he was treated for a week with oral doses of nicotinic acid, which varied from 100 to 500 mg a day. On the seventh day of treatment a sample of his blood permitted a more luxuriant growth of the organism and supported the growth with greater dilutions of blood than previously (tables 1 and 2). The growth of *B. influenzae* in the blood of the two other pellagrins was studied over a period of days. The blood of F H supported growth luxuriously twelve hours after a gram of nicotinic acid was given on one day in five oral 200 mg doses. The blood from the third patient, twelve hours after the same amount of nicotinic acid was given, supported growth well at 1 4,000 dilution and slightly at 1 8,000. Tables 1 and 2 show the amount of growth in the blood of the two groups of persons, but the plus symbols used are arbitrary and minimize the striking differences observed.

#### CONCLUSIONS

1. The present study shows that the blood of normal persons on well balanced diets supports growth of *B. influenzae* to a much greater extent than the blood of

The controls of the culture in autoclaved mediums without added blood were negative in each case. The sterility of the blood that was added was also established.

pellagrins on diets deficient in the pellagra-preventive factor. After nicotinic acid therapy, however, the blood of these pellagrins increased to normal growth-promoting activity. This shows that after nicotinic acid therapy cozymase (or coferment) is significantly increased in the blood of these patients.

2 These observations, plus the observation that prolonged treatment of several hundred pellagrins with nicotinic acid has shown that in many instances the dose must be increased from time to time to prevent recurrences of acute symptoms, support the tentative hypothesis that the therapeutic value of nicotinic acid depends on the synthesis of nicotinic acid nucleotide and finally coenzyme in the body

3 These studies show that the administration of riboflavin is beneficial to certain pellagrins in relapse. Since so many of these specific deficiencies occurring from water-soluble vitamins seem so interrelated, could not the same general biochemical system or systems be involved?

4 From these observations and those previously reported, we continue to recommend large quantities of a liberal and well balanced diet in the treatment of pellagra

#### SUPPLEMENTARY REPORT

Since submitting the preceding for publication, our observations have been extended in several ways. The cozymase content of the blood of a pellagrin with mental symptoms was so low that it would not support growth of the influenza bacillus. However, following the administration of 500 mg. of nicotinic acid daily for two days the influenza bacillus grew in the blood dilutions of 1:4,000 and the symptoms of pellagra disappeared promptly. In three cases of diabetes mellitus in severe acidosis the cozymase content was abnormally low but returned to normal following therapy with diet or insulin or following the administration of nicotinic acid. (We do not imply that nicotinic acid should replace insulin and dietary management in the treatment of diabetes mellitus.) At the suggestion of Dr. John W. Spies, determinations of the cozymase content of the blood of two patients with chronic lymphatic leukemia, three patients with malignant tumors and one patient with Hodgkin's disease were made. The blood from the two patients with leukemia, both of whom had been given roentgen therapy, did not support the growth of the influenza bacillus beyond the 1:1,000 dilution, whereas the blood from the patients with malignant tumors and from the patient with Hodgkin's disease supported growth of these bacilli better than the average. The blood from the patients with leukemia still would not support the growth of the influenza bacillus following the administration of 500 mg. of nicotinic acid daily for two days. The patients with malignant tumors and the normal persons selected for controlled study all appeared in good nutritional state. In contrast to the patients with leukemia, a patient with pernicious anemia in relapse showed normal cozymase concentration in the blood as evidenced by visible growth of the influenza bacillus in dilutions of 1:8,000.

The presence of the V growth factor for *B. influenzae* was also demonstrated in the normal urine studied. "Sterile" normal urine supports growth of the organism in dilutions of 1:10, 1:100 and 1:1,000 in the same autoclaved peptone-blood broth.

## Clinical Notes, Suggestions and New Instruments

### TRAUMATIC TRIPE INTUSSUSCEPTION OF THE ILEUM IN A CHILD

VICTOR A. BADERTSCHER, M.D., LIMA, OHIO

In view of the scarcity of reports in the literature of traumatic intussusception, the following case is presented.

P. N., a schoolboy aged 9 years, was admitted to the hospital with a diagnosis of internal injury. One half hour before admission two wheels of an automobile truck had run over the lower part of the child's abdomen.

On physical examination the temperature was 98 F, the respiration rate 24 and the blood pressure 108 systolic, 76 diastolic. The patient was crying and complained of generalized abdominal pain. The physical changes found at examination were confined to the abdomen which was voluntarily rigid. Over the lower part of the abdomen were numerous cutaneous burns and abrasions.

Laboratory work consisting of urinalysis and roentgenograms of the abdomen, spine and pelvis, offered nothing of positive diagnostic importance.

Since a competent eye witness had seen the child's abdomen run over by two wheels of a motor truck, it was considered advisable to open the abdomen without delay because of probable visceral damage. This was done through a mid right rectus incision under ether anesthesia. The solid viscera and bladder were intact. When the gastrointestinal tract was examined about the middle part of the ileum, the small intestine was found to be intussuscepted in three places at intervals of approximately 20 cm. The intussusceptions were pointed in an abdominal direction and the segments were from 2 to 2.5 cm. long. There was no evidence of obstruction. The segments were easily reduced by gentle traction since no pathologic changes had yet taken place in the intestinal wall. The operation was completed within three hours of the injury and recovery was uneventful.

In reviewing the literature I could find only three cases of traumatic intussusception. The first was reported in 1908 by Stewart<sup>1</sup> of Philadelphia. His patient, a man aged 30, was struck just above the crest of the left ilium by a heavy steel beam. Shortly after the injury he was admitted to the hospital in profound shock. Vomiting, generalized abdominal rigidity and pain, and bloody urine developed and twenty hours later he was operated on. The abdominal muscles were found to be torn from the left iliac crest and a large extraperitoneal hematoma extended into the bladder wall. No viscera were ruptured. There were numerous spastic areas throughout the small intestine. In one place the spastic intestine had passed into a relaxed segment for a distance of 2 inches (5 cm.). The intussusception was reduced and the patient died four hours later in shock.

Le Conte, in commenting on Stewart's experience, described a case he had seen eight years previously of a 9 year old boy who had been stabbed in the left side of the abdomen. When the abdomen was explored under ether anesthesia a direct intussusception about 1 inch (2.5 cm.) long was found in the middle of the small intestine. About 2 feet (60 cm.) distal to the first intussusception two more were found, one direct and the other retrograde. Each was about three fourths inch (2 cm.) long while the sheath or intussusciens covering them was probably 2 inches in length. No signs of inflammation, congestion or change of color of the intestine were present, and reduction was accomplished by very light traction.

Kennedy<sup>2</sup> of London in 1920 reported a case in which a bad injury to the chest was caused by a motor lorry. The patient was admitted to the hospital with subcutaneous emphysema and a rigid abdomen. Within three hours he had vomited three times and appeared very ill. Four and one half hours after the injury the abdomen was opened. An intussusception 1 inch long

From the Department of Surgery, University of Louisville School of Medicine, Louisville, Ky.

2 Kennedy, C. M. Ileal Intussusception Following Severe Trauma. *Lancet* 1: 1008 (May 8) 1920.

was found in the midileum. The proximal intestine was dilated and the ileum distal to the lesion was collapsed. The intussusception was easily reduced and the intestine showed no evidence of injury.

In 1908 Fitzwilliams<sup>3</sup> of London reported a series of 1,000 cases of intussusception, none of which were of traumatic origin. Perrin and Lindsay<sup>4</sup> in 1921 reported a series of 400 cases collected from London hospital records in the eighteen year period between 1903 and 1920. There are no cases of traumatic origin in this series.

Numerous examples of multiple intussusception appear in the literature. Twelve of the thousand cases of Fitzwilliams' presented multiple intussusception. A quintuple intussusception is reported by Baron<sup>5</sup> in a 2 year old boy whose onset was that of severe epigastric pain and cramps with vomiting. At operation five intussusceptions which averaged 13 cm in length, were found in the jejunum within 25 cm. The cause was not evident.

According to Obadalek<sup>6</sup> of Germany, sudden increase in intra abdominal pressure is an important cause of intussusception in children. He reports two cases. Intussusception developed in a girl aged 8 years involving the terminal 40 cm of ileum cecum and ascending colon following a severe paroxysm of coughing. In the second case an intussusception developed in a 4 year old boy while straining at stool. At operation polyps were found in the small intestine. The author states that he failed to produce intussusception experimentally in animals.

#### SUMMARY

1 Traumatic triple intussusception of the small bowel was found at operation in a child whose abdomen was run over by an automobile truck.

2 Three previous cases of traumatic intussusception have been reported. Numerous references of multiple intussusceptions appear in the literature.

3 Increased intra-abdominal pressure is suggested as an etiologic factor in intussusception.

#### POSSIBILITY OF FAULTY DIAGNOSIS OF DIABETES IN PATIENTS TAKING THIAMIN CHLORIDE

RUTH S. HART, M.D. AND LOUIS E. WISE, PH.D.  
WINTER PARK, FLA.

The first morning specimen of urine collected from the patient, Mr. L. W., showed very marked reduction of Benedict's solution. The following morning the fasting blood sugar content was determined and found to be 90 mg per hundred cubic centimeters. The following day after a breakfast high in carbohydrates the urine was again examined and showed no reduction. At intervals thereafter, with a continued daily dose of 4 mg of thiamin chloride, the urine either showed traces of reducing substances or no reduction whatever. The medication of the patient, begun a month prior to the first urine examination, was two tablets of thiamin chloride prior to each meal (i.e. 6 mg a day) three 1½ grain (0.1 Gm.) tablets of theophylline with ethylenediamine and 3 grams (0.2 Gm.) of phenobarbital daily. Neither theophylline with ethylenediamine nor phenobarbital reduces Benedict's solution.

On the other hand 10 mg of pure thiamin chloride in 1 cc of distilled water reduced Benedict's solution only slightly giving an atypical yellow precipitate.

Whether or not thiamin chloride alone was responsible for the reducing substance found in the urine originally examined still is problematic.

Morning specimens from three other patients who were on at least 6 mg of thiamin chloride daily were examined and showed no reduction of Benedict's solution. Of these one patient was taking in addition to thiamin chloride an uncertain

amount of morphine. One other was taking 40 grains (2.6 Gm.) of acetylsalicylic acid daily.

The following possibilities in this case must be considered:

(a) Storage of thiamin chloride, with marked elimination at intervals.

(b) Elimination of oxidizable degradation products of thiamin chloride.

(c) Elimination of oxidizable degradation products of theophylline with ethylenediamine or phenobarbital or both.

(d) Lowering of the renal threshold to dextrose through the agency of thiamin chloride.

The question arises of the accuracy of Benedict's test for measuring dosage of insulin with patients taking thiamin chloride.

#### CONCLUSIONS

1 Pure thiamin chloride will reduce Benedict's solution in vitro.

2 Urine of one patient receiving 6 mg daily of thiamin chloride reduced Benedict's solution despite a blood sugar of 90 mg per hundred cubic centimeters of blood.

#### CALCANEAL SPURS

SIMPLIFIED METHOD OF TREATMENT

JAMES R. REGAN, M.D., MILWAUKEE

Painful heels have for purposes of treatment been classified into those cases in which a calcaneal spur can be demonstrated roentgenographically and those in which no spur is present. In most cases in which no spur is demonstrable, relief is obtained by the use of well fitting supports applied to the plantar area of the foot which relax the structures. In those cases in which a calcaneal spur can be demonstrated and in which there is pain (many cases of calcaneal spurs cause no symptoms) treatment has been both conservative and radical. The conservative treatment consists of avoidance of weight bearing as well as the use of certain types of heels, shoe correction and the use of soft insoles. The radical treatment is concerned with either the surgical removal of the spur or some other method designed to remove weight bearing on the point of the spur, such as the rotation osteotomy as practiced by Steindler and Smith.<sup>1</sup> The latter procedure is, in the words of the authors, "too radical a procedure to be used in any but the most recalcitrant type of case." I have long since discontinued the use of the simple removal by chisel of the spur, since in these cases a very painful periostitis develops soon after the operation which is of a more disabling degree than the spur itself.

Based on work performed on the obliterative therapy in varicose veins and the like, a simple and effective treatment has been evolved and is being reported here. It was found in those cases in which operation was done that at the tip of the spur a bursa had formed. It seems reasonable to believe that a bursa formed in an unnatural place, the result of irritation, being the causative factor for the pain in calcaneal spurs. Many calcaneal spurs cause no symptoms whatever and are found purely by accident.

For the past five years in those cases of calcaneal spurs which were painful and which did not respond to the use of well fitting supports, felt pads, shoe correction and the like the following procedure was carried out. At the point of greatest tenderness an ordinary hypodermic needle was thrust through the skin on the plantar area of the os calcis until osseous tissue was reached. Then a few drops of 2 per cent procaine hydrochloride was injected followed in a few moments by 0.5 cc of sodium morrhuate in 5 per cent benzyl alcohol. The relief from the symptoms was rapid as well as fairly well prolonged. Up to the present time thirty-three patients with painful heels due to a calcaneal spur have been treated in this manner and of the thirty-three only two failed to obtain relief following the first injection. It was necessary in one case to perform four subsequent injections before relief was obtained. One patient has had no relief from this treatment. The relief obtained usually lasts for between two and three years after which another injection may be given.

<sup>3</sup> Fitzwilliams, D. C. L. Series of 1000 Cases of Intussusception. *Lancet* 1: 628 (Feb. 29) 1908.

<sup>4</sup> Perrin, W. S. and Lindsay, E. C. Four Hundred Cases of Intussusception. *Brit. J. Surg.* 9: 4671 (July) 1921.

<sup>5</sup> Baron, Charles. A Case of Multiple Intussusception. *Kentucky M. J.* 30: 406-407 (July) 1932.

<sup>6</sup> Obadalek, Walter. Darmeinwulstung und intraperitonealer Druck im Kindesalter. *Deutsche Z. klin. Chir.* 159: 160 1934. *abstr. J. A. M. A.* 102: 14-4 (April 28) 1934.

<sup>1</sup> Steindler, A. F. and Smith, A. R. Spurs of the Os Calcis. *Surg. Gynec. & Obst.* 66: 663 (6) (March) 1938.

The use of this solution has not resulted in any bad effects. I would not presume to be able to inject the material into the small bursa at the tip of the spur, as this is not necessary. If the solution is injected in the peribursal tissues, obliteration with organization of the bursa takes place. The irritation of the chemical injected causes an inflammatory process to be set up, which eventuates in the organization of the resultant into fibrous tissue. There is some slight pain after injection, which usually passes away within twenty-four hours.

#### SUMMARY AND CONCLUSIONS

1 A simple and effective method for the treatment of painful heels due to calcaneal spurs was used in thirty-three cases with thirty-one excellent results, in one case four injections were necessary and in one case there was no relief whatever.

2 The period of relief usually lasts from two to three years.

3 Only those cases in which the painful heel was due to calcaneal spur are included.

4 Sodium morrhuate in 5 per cent benzyl alcohol is used to obliterate the bursa at the tip of the spur.

5 It is my opinion that removal of the spur does not promise the relief that more conservative measures do; also the rotation osteotomy is very radical and a difficult procedure.

### Special Clinical Article

#### THE PERENNIAL DISPUTE IN THE TREATMENT OF PROSTATISM

CLINICAL LECTURE AT SAN FRANCISCO  
SESSION

FRANK HINMAN, M.D.  
SAN FRANCISCO

Prostatism is caused by one of three conditions: median bar, hyperplasia or cancer. It is treated by one of three routes: the transurethral, the suprapubic or the perineal. This triebleness of kind and approach is confusing and a cause of contention. To differentiate a median bar from hyperplasia, either of which may be associated with cancer, and to recognize cancer when it occurs alone as well as when it is so associated is the problem of diagnosis. None of the three conditions can be cured without surgical intervention. To treat each kind of prostatism therefore by a transurethral, a suprapubic or a perineal operation is the choice of surgery, at least in theory. This reasoning may be false, since it is not followed in every practice. Some surgeons never choose a twofold or threefold plan of treatment but fit one method to all conditions. It follows that the diagnostic problem weighs lightly with them. These surgeons, however, are not crsuits. They are just as honest and sincere as those who elect a method which in theory may fit the condition better. They either believe the one method to be adequate for all three kinds of prostatism or admitting the logic of choice in treatment, have discovered by practical experience that sticking to this one method for all conditions gives them better results than using other methods. The skill which they have acquired in this one way of treatment overbalances the theoretical advantages of the other ways, in which they have been found by sweet and sorrow to be unskilled. Patients with prostatism ask their medical advisers

and these in turn search the medical literature and quiz their urologic confreres for an answer to the questions: Are these differences in urologic practice insignificant? Is the method of resection really adequate for all conditions? Does skill of performance outweigh the theoretical advantages? A simple comparison of results seems all that is needed in answer, but, just as a close or tied score does not tell the full story of the game, so such a comparison fails to reveal the truth about prostatism. It is not so simple. Much depends on the point of view acquired by training and experience. As the points of view differ, so will the answers differ. Perhaps a glimpse of the truth, so easily obscured in practice, may be caught by an open consideration of the three points of view. As true an insight into the problem, therefore, as is possible at present may be given by drawing up three declarations showing, for each way of approach, the pleas and replies, the reasons for and the arguments against and the evidence and counterevidence. In order to make such a presentation clear and simple, the diagnostic and clinical differences between the three common conditions producing prostatism should be known. Conceding that the surgeon's knowledge of these differences is ample, certain points of differentiation are worth emphasizing.

#### DIAGNOSIS OF THE CONDITION WHICH CAUSES PROSTATISM

The median bar or contracture at the vesical neck occurs in men under 50 about as frequently as does hyperplasia or enlargement of the prostate in men over 50. Long before the advent of electrical resection the bar was recognized as an entity distinct and different from hyperplasia and was treated successfully by the transurethral punch of Young or by suprapubic excision. Such bars are fibrous and glandular (fig. 1). They usually form a single joist from wall to wall, but they may be of ring type and encircle the neck, forming a contracture. Fibrous bars and contractures occur in women as well as in men. In men the glandular type of bar is similar pathologically to hyperplasia (fig. 2). Size and position distinguish the two. Single posterior enlargements of the prostate may be median in position, subcervical (beneath the neck) or subtrigonal (beneath the trigon). Such enlargements are called commissural when they connect coexisting lateral enlargements. Any of these may form a rounded mass which projects into the urethra or the bladder, producing a ball valve type of obstruction, and when small they are usually grouped with the median bars. A localized enlargement of the anterior lobe sometimes acts similarly as a ball valve. Enlargements also may be localized to the median or to the right or left lateral position. Such single isolated lobes are rare and belong with the hyperplasias. Median bars produce some of the most marked changes of back pressure, more even than hyperplasia does (such as large vesical diverticula, hydro-ureters and hydro-nephroses).

Enlargement of the prostate, or hyperplasia, is distinctly periurethral and supramontane. The glands surrounding the portion of the urethra between the level of the verumontanum and the bladder undergo this change (fig. 3). By their enlargement the surrounding and outer glands of the prostate, which never undergo such change to any marked degree, are compressed into the form of a glandular covering or layer

familiar to surgeons using the suprapubic and the perineal approach as the false capsule which is left after enucleation of the enlargement (fig 4) Enlargements of any size are compact and removable in one piece A trilobed bilateral-commissural combination is

Fig 1—Changes from normal with median bar

the common form, though all sorts of combinations occur Enlargements distort and elongate the supramontane portion of the urethra or protrude into the bladder, dilating the sphincter

The median bar is easily recognized with the cystoscope, which shows a bas-fond or sulcus between bar and interurethral ridge and trabeculations cellules and other evidence of back pressure Recto-urethral thickening is absent, but there is a distinct overriding of the bar by the beak with a jump when the cystoscope with the beak turned down is drawn back into the urethra, and when the operator attempts to push the beak back into the bladder it usually catches on the bar This is best demonstrated with a finger in the rectum pressing on the vesical neck

Isolated lobes and true hyperplasia are recognized by means of touch, sight and measure Rectally in hyperplasia the median prostatic furrow and notch are filled in and obliterated and the lateral sulci are deepened Cystoscopically in addition to the changes of back pressure in the bladder sulci between lobes indicate the type of intravesical enlargement (fig 5), and when the cystoscope is withdrawn into the urethra the extent of encroachment of the prostatic urethra by lateral and median lobes is visible The extent to which the enlargement has lengthened the supramontane portion can be measured by marking on a ruler held parallel to the cystoscope the point opposite the water vent at which the extreme intravesical projection is in view, when the outer intraprostatic limits are brought to view (usually at the level of the verumontanum) as the cystoscope is pulled out this second point is marked

on the ruler The distance between these two points measures roughly the length of the enlargement (fig 6) Rectal and recto-urethral palpation indicates its width or thickness

Cancer of the prostate is a common form of malignant process As a cause of death it stands for men well above cancer of the uterus for women Sufferers under the age of 50 are the exception, the majority are over 60 (fig 7) Cancer of the prostate gives no early manifestation but creeps in silently and insidiously and as a rule is well advanced before being suspected The disturbance of urination, the common cause of the examination which reveals the cancer results from an associated median bar or, oftener, from hyperplasia (in 20 per cent of cases), either of which usually is coincidental Occasionally when carcinoma occurs without these other changes the prostatism, bleeding, pain or other complaints have arisen only after extension of the cancer into the urethra or the neck of the bladder or around local nerve trunks Metastases even at a distance have been found without local symptoms or signs This symptomless, hidden nature of the disease largely accounts for the failure to make early diagnoses The slogan "early diagnosis and radical removal" is barely audible in this branch of surgical practice Many urologists are outspoken in their belief that cancer of the prostate is always fatal, they know for a fact that they have never cured a patient Pessimism of this kind accounts for the other failures to make an early diagnosis This "what's the use" attitude

Fig 2—Similarity of glandular bar and subcervical lobe which acts as a ball valve

loses its fatalism with the thought that complete removal will cure cancer that it will has been proved repeatedly, although by only a few urologists The truth thus indisputably established warrants an effort both to improve the dismal record of early diagnosis and to take advantage of such diagnosis by prompt and radical surgical intervention

One form of cancer of the prostate, the common form (probably nine in ten) starts in the posterior portion. From this area it grows by extension to involve seminal vesicles, vasa the neck of the bladder and the hyperplasia when coexistent, or it spreads to a distance through the lymph or blood streams, causing

cancer and hyperplasia the primary lesion was peripheral, with invasion of the hyperplasia, and in how many it was central, with extension from the hyperplasia. A diagnosis made after such extension is not an early diagnosis.

The clinical diagnosis of carcinoma of the prostate is at all definite only when the lesion is advanced and incurable. An early lesion may be suspected clinically but is proved only with the microscope. Suspicion is aroused by the finding, on rectal palpation, of an area of stony hardness, which must be distinguished from inflammatory induration and calcification. Not all carcinomas are scirrhus and stony hard. Medullary and glandular types may be soft or even semifluctuant and are suspected because of the absence of the usual causes of these changes. The uncommon

Fig. 3—The probable origin of hyperplasia from periurethral and submucosal glands or from primary myoma invaded later by the ducts of these glands (Denning)

metastases, the most frequent being perineural, in lymph glands and in bones, particularly the vertebral and pelvic. A diagnosis made after such extension or metastasis is not an early diagnosis (fig. 8).

Another form of prostatic cancer (probably one in ten) starts within hyperplasia as a form of malignant degeneration and, with growth, extends into surrounding structures or metastasizes, just as the common form does. When advanced it cannot be distinguished

Fig. 4—Cavity with its false capsule after enucleation en masse of bilateral and commissural enlargement the common type

from the late stages of the ordinary form associated with hyperplasia. Serial sections of enlarged prostates removed suprapubically or perineally and wholly unsuspected of cancer will show early lesions of a malignant process of this type in about 5 per cent of cases. It is impossible to know in how many cases of advanced

Fig. 5—The method of exact diagnosis of the type and size of enlargement

lesion, which begins as a form of degeneration within hyperplasia, is never recognized early by palpation and even in an advanced form—after local extension and distant metastasis—may be missed entirely by the examining finger in the rectum. Early recognition even of the common form which causes stony hardness is rare. When first seen, therefore, most cancers are in an advanced stage. Cancer creeps in with the patient unaware, and one may well ask: Who is to blame for its late discovery? In how many cases would it have been diagnosed earlier had the patient when he reached the age of 50 adopted the practice of having a complete physical check-up twice a year? Should family physicians keep a record and remind patients of the time for examination, as dentists do? Are the teeth the only part of the body for which "a stitch in time saves nine"? Even though rectal examinations were made regularly, it is safe to say that not all cancers would be recognized early, none of those which start within hyperplasia would be discovered, and many of

the common forms which start in the outer glands would be missed at first or suspected lightly and allowed to progress until too late for cure. As already stated, the clinical diagnosis of an early cancer of the prostate is always merely on suspicion. Only the microscope can be definite. This uncertainty of early diagnosis leads to wrong-doing in two ways. Procrastination, putting off a decision when in doubt, is a natural fault, and of course mechanical injury from repeated manipulation and massage follows because of this doubt. The one, by delay, causes loss of opportunity, the other, by spreading cancer, destroys all hope of a cure. What can be done? Vigorous massage of inflammatory indurations causes their disappearance, which disproves cancer. If cancer exists, however, all manipulations should be gentle. No surgeon mauls and squeezes a malignant process elsewhere. An experienced finger learns to distinguish fairly accurately the induration of lesser degree caused by inflammation from the extreme induration of cancer. An immediate biopsy is always in order on the first suspicion. When the surgeon is reasonably sure of the diagnosis, biopsy can be performed after the patient has been prepared for radical

of the urethra or at the vesical neck which looks infiltrated, hard and nodular. This can be done at the time of cystoscopic examination. However, as in biopsy with needles, a negative report is not conclusive.

The three conditions—median bar, enlargement and cancer—are not always unitary and distinct. As previously explained, cancer commonly occurs with bars and

TABLE 1—Causes of Prostatism

1 Median bar	5 Inflammation
2 Hyperplasia	Non-specific
3 Neoplasm	Acute
Carcinoma	Chronic
Sarcoma	Suppurative (abscess)
Leiomyoma	Specific
4 Cysts	Tuberculous
	Actinomycosis
	6 Calculi

enlargements, and this association is usually coincidental. Other conditions also complicate bars and enlargements, and their neglect or recognition in the surgeon's plan of treatment makes his standard of cure low or high. Sometimes one of these other conditions is the sole cause of the patient's urinary difficulties. Table 1 shows the need of differential diagnosis and the conditions to be considered. Inflammation is the most troublesome condition and is often aggravated by calculi. It alone may cause prostatism, even to complete retention. Commonly, however, it occurs with and complicates the three common causes of prostatism, particularly enlargement. When inflammation is a complication, no method of removal gives a high standard of cure if infection persists and causes a continuation of the burning and frequency. The amount of residual urine measures the degree of relief from obstruction, but this is surely not the only evidence of cure.

#### ATTRIBUTES OF THE METHODS OF TREATMENT

Knowledge of the clinical differences between median bar, hyperplasia and cancer, of the variability in size and position of hyperplasia and of the two types of cancer which has been briefly outlined, is only the first step toward justice and truth in the dispute as to treatment. The technical difficulties, the risks involved and the benefits derived from each of the three

Fig 6—How the length of the enlargement can be measured

operation by perineal exposure, on microscopic confirmation the radical operation can be completed or, if the diagnosis is disproved, the wound can be closed and no harm is done. If the surgeon is not sufficiently sure of the diagnosis, needling of the area of induration may provide a piece of tissue which shows cancer on microscopic study, and then radical operation can be advised with confidence and done as soon as convenient. However, a suspicious area into which needles have been thrust by way of the perineum should not be forgotten if biopsy had a negative result. The method of biopsy with needles is too uncertain to be taken seriously if the result is negative. Of course such biopsy can be repeated but, if cancer is really present repeated puncture by needles cannot be harmless. The patient should be followed closely and reexamined regularly but gently. Should suspicion persist or be increased by local changes, there should be no hesitancy in placing the facts before the patient and advising an exploratory operation with the plan that if the pathologist finds cancer radical removal will be undertaken at once. If cancer is not found, the relief to the patient and his surgeon offsets all the trouble, this is the only result, since there is no risk in perineal exposure and simple biopsy. A third method of biopsy when cancer is suspected is by removal with the resectoscope of a cylinder of tissue from the area in the prostatic portion

Fig 7—Age incidence of cancer of the prostate

surgical approaches must also be considered. Even if equal skill in their use is assumed for the purpose of comparison differences of opinion will remain for the simple reason that the majority of disputants are very one-sided. Their opinions are biased. They operate by the method which best suits them, too often the only method of which they have any practical knowledge. Naturally they are vigorous in defense of this practice. Skill in any of these approaches is not

acquired by reading and observation. It requires practice. The average surgeon of today lacks the opportunity of learning more than one method. Educated in a center in which only the perineal approach is used, he may never have done a suprapubic enucleation or even have seen one, and vice versa, although both camps do resections. Trained by a resectionist his knowledge of perineal and suprapubic operations of the prostate may be nil. This is no exaggeration. Recently a young man from a great medical center, on the usual tour before entering urologic practice, told me that he had never seen a perineal prostatectomy. Limitation of training and the one-sided outlook which follows cannot be disregarded when it comes to drawing up declarations for or against a method.

I shall disregard for the moment this warp and bias and, without partisanship or prejudice, make an honest attempt to enumerate truthfully the difficulties of performance, the risks involved and the benefits derived.

ever before. It can be mastered only by trial and error, and few medical centers provide an opportunity for this. The modern method of suture and closure controls hemorrhage, thus lessening the risk, and shortens the stay in the hospital to an average of twenty-one days. The surgical risk is low, the mortality being from 1 to 8 per cent, with an average of 3 per cent. The functional risk in the hands of the expert surgeon is high. The fear of impotence, of incontinence and of fecal fistula is overcome only with complete mastery of the details of technique. The functional results are equal to those obtained with the suprapubic approach and superior in many ways to those achieved with transurethral resection. The greatest advantage of the perineal method is in the treatment of cancer, for it is the only method which cures cancer. It is the only method which permits exposure for biopsy when cancer is suspected, and, furthermore, its use in a modified form often gives a higher degree of relief than does any other form of treatment to the

patient with a cancer which cannot be radically removed. Several modifications of technique are in use both for hyperplasia and for cancer. The modern method for the treatment of hyperplasia, cauterization *en masse*, structural repair by suture and closure without packs or drains, is an improvement in technique unknown and unappreciated by surgeons who have never used it.

The transurethral approach is the most popular, and its greatest fault lies in its very popularity. The reputed ease of performance, the supposed safety, the high pressure advertising of instrument makers and the enthusiastic adoption for trial by practicing urologists everywhere at first deceived the profession and

Fig. 8—The difference and similarity in the way the two types of cancer may spread from the primary place of origin.

The suprapubic approach is suitable for hyperplasia and is rarely if ever used for the removal of a median lobe or for cancer, except unintentionally when the neoplasm is concealed within hyperplasia. There are three chief modifications of technique, the one stage operation, the two stage operation and the more modern operation, which may be in one or two stages, with repair by suture and closure. The difficulties of technique, except when closure is attempted are not great. Failure to remove all the hyperplasia, which is not infrequent, usually arises from inexperience. The surgical risk is high, the mortality being from 4 to 20 per cent, with an average of 8 per cent. The period in the hospital is long, averaging from thirty to forty days, but is shortened considerably when the modern method of closure is used successfully. A persistent urinary fistula is uncommon. Structural defects also are rare. As a rule the functional results are both good and permanent.

The perineal approach is difficult to master and should never be attempted unless it is mastered. The operation, however, is performed more generally today than

the public. General practitioners and surgeons bought instruments and tried out their use even as an office procedure, patients soon began to demand the "electrical method," so that surgeons sometimes attempted it for this reason rather than for the fitness of the condition to the method or of themselves to perform it. Fortunately this burst of enthusiasm for transurethral resection has spent itself. The method does have some disadvantages, and the public has paid a heavy price for this knowledge. Let me review it briefly. Transurethral resection requires no particular surgical training, it is true but it does require a high degree of cystoscopic skill and experience. It is neither a simple nor a benign procedure and can be mastered only by trial and error. With the procedure in the hands of an expert the risk of death may be 1 per cent or less but the figure has reached 30 per cent or over, for example in some county hospitals. The average mortality throughout the country is probably about 4 per cent. This is no supersafety, and the figures quoted are of only relative value because the various series of cases on which they are based are not comparable.

to series reported by surgeons using the suprapubic or the perineal approach whose statistics, however, are themselves comparable. Is this criticism unjust? Resectionists have reported several of the largest series on record, consisting of thousands of patients operated on in one decade, a number which no surgeon has

Fig 9—Specimen after radical prostatectomy and vesiculectomy (an expected cure)

equaled in two or three decades when operating suprapubically and perineally. Either there has been a decided increase in the incidence of enlarged prostates since the advent of the resectoscope, which seems absurd, or the large series reported by the resectionists include patients with median bars, isolated enlargements and small hyperplasias never cut with the knife by the surgeon. Almost all such patients are good risks, and when they are included in a large series the mortality should be much reduced.

An undisputed advantage of resection is the short period of disability. Exclusive of the preparation by catheter or otherwise often omitted nowadays, a week or ten days in the hospital is the average. This means a considerable saving of time and money. Patients who require more than one resection, however, as those with large prostates usually do, and patients who return in a few years for another resection gain little by avoiding operation.

The disadvantages of resection, even when well done, are the frequency of a recurrence of the prostatism, the unsatisfactory results obtained with hyperplasia complicated by infection with or without prostatic calculi, and the total absence of cure when cancer of either type is present. Furthermore, resection has its own functional risks. The journey afterward is not always smooth and uncomplicated. Incontinence, for example, is just as frequent after resection with poor workmanship as after unskilful removal through the perineum, the enormous sale of penile clamps in recent years suggests that it is more frequent.

No true estimate of the number of patients who have a return of prostatism after resection is possible at

present. The likelihood of return will vary with the thoroughness of the original removal. The experience of surgeons who use the suprapubic and perineal approach teaches that hyperplastic areas and nodules left behind at operation will grow and in time reach a size which causes obstruction. The need of complete removal, best secured by enucleation *en masse*, is the lesson learned by these surgeons. One is constrained to question the ability to resect completely enlargements of large size, and few resectionists have complete resection in mind even for smaller glands, therefore a high rate of recurrence is inevitable.

Infection of the prostate, particularly when there are stones in the gland, greatly reduces the efficiency of resection. Most patients, even with a channel bored through the hyperplastic glands which enables them to empty their bladders freely and completely, still carry the burden of urinary frequency and sepsis. In theory the enlarged prostate full of stones and infection is best treated perineally, sometimes by radical removal. A word is in order in this connection on the resection of

Fig 10—Specimen after a partial radical operation for cancer which had invaded the vas deferens beyond the reach of removal. Most patients after this operation are comfortable urologically for the remainder of life.

the small hyperplasia, the beginning enlargement which as yet causes little and variable obstruction. Patients with this condition were treated by massage and prostatic massage before, and many got along comfortably without ever requiring operation. The gain by resection is questionable so far as actual comfort and prolongation of life are concerned. Often resection may not have been needed. When the condition of early enlargement is complicated by infection with or without stones, this

infection may be the cause of symptoms which will disappear under treatment. Should not prophylactic resection, the removal of an early enlargement before it causes trouble, therefore be done advisedly?

The futility of resection for cancer of the prostate is a real disadvantage. Untaunted in perineal operations, the hands most skillful in transurethral resection are

TABLE 2—The Three Methods of Treatment

	Suprapubic Operation	Perineal Operation	Transurethral Resection
Mortality % extremes	4 to 20	1 to 5	—1 to 30 (of only relative value in comparison)
Average	8	3	4

tied and helpless. Palliative resection in the late stages of malignant disease is the only service possible for the large group of patients with cancer of the prostate, and the little benefit derived may be short lived. Recurrent hemorrhages and obstruction necessitating repeated resections until death delivers the victim from misery. Surgeons now know the limitations of roentgen therapy and of the use of radium and that cure is assured only by radical removal. Unattainable as radical removal is for surgeons not trained to do it, there is no need for an early diagnosis of cancer. To such practitioners of urology, palliative measures as their need arises are just as satisfactory as the radical method, of which they have heard but have no first hand knowledge. They believe that early diagnosis is so rare and a cure so infrequent as hardly to be worth considering. Is this reasoning valid? Is this a sound argument?

The truth of the matter remains that likelihood of recurrence, poor results when infections and calculi coexist and total unfitness for the cure of cancer form objections to the method of resection aside from all slips and mishaps of technic.

The attributes of the three methods of treatment are summarized in table 2.

#### CHOICE OF METHOD

Obviously the query in the minds of nonparticipants cannot be answered satisfactorily at present. Knowledge of the marked differences in the three common conditions causing prostatism and of the chief attributes of the three methods of treatment is common. The picture of truth envisioned out of this knowledge by each individual will be colored by his particular bent of mind. Persons of a mind with me see logic in the choice of method to suit conditions and since the facts fail to establish the adequacy of one method for treat-

ing the three types, lack of logic in fitting one method to all conditions. Describing practice for theory, one would make the choice somewhat according to table 3.

#### CONCLUSION

Presupposing skillful performance, in theory the transurethral method is most suitable for fibrous and glandular bars and for certain of the smaller hyperplasias producing prostatism. The perineal method, with its low risk and absence of recurrence, is preferable for larger glands, many of which harbor cancer. Its more general use on suspicion will increase the number of early diagnoses and cures of cancer. The suprapubic method carries the greatest surgical risk and is applicable only to benign enlargements. On the other hand, in practice the suprapubic method is easiest to learn and carries much less risk of functional disaster if the patient survives. The perineal method, while safe surgically, is highly technical and difficult to perform and is followed in fear of the sphincter and dread of the rectum because injury of either means odium to the surgeon and misery to the patient. Such injury, however, has been exaggerated. Both rectum and sphincter at rare need can be repaired and need of perineal repair has not been infrequent for certain transurethral mishaps. Thus so-called nonsurgical

TABLE 3—Suitability of the Methods, When Skillfully Performed to the Conditions

Clinical Condition	1 Suprapubic	2 Perineal	3 Transurethral

2 Late (same as common cancer with prostatism)	+	+++ (partial radical)	+++ (palliative temporarily)

\* May fail to remove cancer concealed in hyperplasia if incomplete.

method requires a prolonged apprenticeship of trial and error before mastery. It is not always curative even for median bars. Sometimes infection persists. Some patients dribble afterward, and some complain of an ejaculatory backfire. Against the questionable element of safety and the saving of time in its favor is a method of treatment for hyperplasia must be set the disadvantage of recurrence and the poor results with complicating infections, and as a method of cure of cancer it is futile.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION  
OF THE FOLLOWING REPORT

HOWARD A CARTER Secretary

### COLLWIL INTERMITTENT VENOUS OCCLUSION APPARATUS ACCEPTABLE

Manufacturer U M A, Inc, 111 Greene Street, New York

The Collwil (Collens-Wilensky) Intermittent Venous Occlusion Apparatus is designed for the treatment of peripheral vascular diseases of the extremities. A pneumatic cuff is applied to the proximal part of the extremity, supplying intermittent interruptions to the venous return.

The appliance consists of a motor driven pump which supplies air to a pneumatic cuff. Compression is regulated by a pressure measuring indicator. Any desired variable pressure of from 20 to 110 mm of mercury is imposed on the proximal portion of the diseased extremity and restricts the return of venous blood. It is claimed that sufficient pressure is applied to constrict veins but not enough to interfere with arterial filling.

A suitable timing mechanism is incorporated in the device, which maintains a pressure for a given period of minutes, after which a release valve, actuated electrically, causes an automatic deflation of the cuff. It is claimed that during the release period an increased arterial flow through the extremities occurs as a reactive hyperemia giving rise to the following effects in the treatment of organic peripheral vascular obstruction, for example (1) relief of pain, (2) increase of skin temperature of the extremity and (3) increase in vascularity, permitting amputation at lower levels.

Collwil Intermittent Venous  
Occlusion Apparatus

In the opinion of the Council, this device is comparable in effect to other passive vascular exercise units already accepted. Some of the indications for the use of this apparatus appear to be acute vascular occlusion, frost bite, vascular diseases with major involvement of the large blood vessels and thrombo-angitis obliterans without extreme capillary stasis. Contraindications appear to be thrombophlebitis, cellulitis or lymphangitis (acute or subacute), extensive destruction of the arteriolar or capillary vessels, advanced thrombo-angitis obliterans with capillary stasis and venous thrombosis.

The results of the investigation conducted by the Council appeared to substantiate the foregoing indications and contraindications. In the opinion of the Council, the performance of this unit is satisfactory from a mechanical standpoint. The duration and the amount of pressure are controlled automatically and may be adjusted to the requirements of the individual patient. During three months of constant use the machine did not require any repair or adjustment.

From the physiologic standpoint, the production of the intermittent venous hyperemia to increase peripheral circulation seems sound and tests performed indicate that both surface temperatures and the oscillometric curves increase after the application of this method. During venous occlusion there is a filling and stretching of the venocapillary bed while during release a reactive hyperemia takes place, bringing about vasodilatation. There is, however, no provision made in this type of treatment to empty the vascular bed effectively and for this reason a certain amount of continuous venous stasis exists.

In the opinion of the Council this device has a limited therapeutic usefulness and the Council reiterates that this is only a form of physical therapy to be used in conjunction with other methods of treatment in peripheral vascular diseases.

In view of the foregoing report the Council voted to accept the Collwil (Collens-Wilensky) Intermittent Venous Occlusion Apparatus for inclusion in its list of accepted devices.

### REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING  
REPORT

PAUL NICHOLAS LEECH Secretary

### PRESENT STATUS OF PICROTOXIN IN POISONING BY THE BARBITURATES

During the past seven years reports have accumulated in the literature concerning the use of picrotoxin as an antidote to poisoning by the barbiturates. Attention was first called to this matter in a study by Maloney, Fitch and Tatum<sup>1</sup> in 1931. This and subsequent reports have established the fact that animals survive otherwise fatal doses of the various barbiturates when treated with picrotoxin.<sup>2</sup> Linegar, Dille and Koppány,<sup>3</sup> by the use of divided doses of barbiturates, secured recovery from as much as four times the fatal dose of barbital sodium by treatment with picrotoxin. It appears that picrotoxin is not as efficacious in the case of some of the barbiturates as in that of others.<sup>4</sup> The doses of picrotoxin required in this treatment are many times those which are fatal in the normal animal. Nevertheless, no structural or functional damage appears to have resulted from this treatment in animals.

The details of events in the course of animal experiments show that it is necessary to poison the animal with picrotoxin in order to elicit the antagonism. What results when the two drugs are given together is not a direct reversal of the depressed state but a combined form of poisoning by picrotoxin and the barbiturate with a mixture of depression and stimulation, from which within a given range of doses the animal ultimately recovers. Rapid restoration of consciousness by the picrotoxin is not possible except during mild barbiturate depression. During severe poisoning, even doses of picrotoxin that induce convulsions fail to reestablish consciousness directly, although in the end the recovery from the barbiturate appears to be faster than without picrotoxin.<sup>5</sup> Picrotoxin raises the oxygen consumption (rat) which has been depressed by the barbiturate, although Krantz, Carr and Beck<sup>6</sup> have shown that this is not the direct mechanism by which the depression of the nerve centers is abolished. The picrotoxin appears to exert its influence against barbiturate depression partly by cortical stimulation but chiefly by stimulation of medullary centers assisting in the maintenance of adequate respiration and circulation.<sup>7</sup>

Sporadic attempts have been made to treat human beings with barbiturate poisoning by means of picrotoxin. Six reports dealing with this subject were available for this report, these describe twenty-seven cases of barbiturate poisoning in some detail. Very large doses of picrotoxin were used. Rovenstine<sup>8</sup> administered total amounts of from 60 to 1820 mg (about 1 to 30 grains) during the course of treatment in different cases in which recovery occurred. These doses, it is indicated, produce signs of stimulation—muscle twitching, convulsive movements and increased respiration—but in severe poisoning, even after convulsive doses, consciousness remains in abeyance for several hours.

8 Rovenstine E A. Antidotal Action of Picrotoxin in Acute Intoxication by the Barbiturates. Manuscript submitted to the Council on Pharmacy and Chemistry.

In all these reports the authors have expressed the belief that treatment by picrotoxin was responsible for the fact that the patients did not take longer to recover or that they recovered at all. It is well known that strictly comparable controls are difficult to obtain in clinical poisoning because of the great diversity of factors over which, under the conditions of human poisoning, there can be no control. Nevertheless, it is possible to compare the course of events in a series of treated with untreated cases at a sufficient number of points to obtain reasonable support for inference. The most direct objective

\* Depression in this case was never severe and possibility of a psychic affair was considered by the author

indications concerning the clinical value of the antidote in cases of barbiturate poisoning should be supplied by a comparison of (1) the doses of the barbiturates, (2) the severity of the symptoms of poisoning, (3) the speed of recovery and (4) the mortality rates.

It would indicate that the antidote was effective if several subjects recovered from doses of barbiturates which exceeded considerably the largest doses known to have been survived without picrotoxin, if the symptoms of barbiturate poisoning in the treated cases that recovered were of such kind or severity as are seen only in otherwise fatal cases, if the duration of the poisoning was considerably shorter in the treated cases or if the mortality rate from barbiturate poisoning began to fall off since the use of picrotoxin has been popularized.

The twenty-seven cases of barbiturate poisoning treated with picrotoxin have been analyzed with the foregoing points in

view. Among these there were five deaths: one after 500 grains (32 Gm) of barbital and in one after an unknown dose of phenobarbital, in two cases neither the dose nor the kind of barbiturate was known. The fifth fatal case (possibly due to hemorrhage and surgical shock) was that of a patient who received 3 grains (0.2 Gm) of nembutal (pentobarbital sodium) in the evening without untoward effects, and 1½ grains (0.1 Gm) the following morning shortly before an operation with general anesthesia. There was marked delay in regaining consciousness and picrotoxin appeared to have influenced temporarily the degree of depression, but there seems to be no apparent reason for considering this case of barbiturate poisoning. There remain, therefore, twenty-two cases in which recovery occurred from barbiturate poisoning during the use of picrotoxin. The essential facts are summarized in the accompanying table.<sup>9</sup>

#### DOSES

The doses of the barbiturate from which these patients recovered were very large, amytal sodium from 90 to 144 grains (6 to 9 Gm), phenobarbital or its sodium salt, from 75 to 90 grains (5 to 6 Gm), barbital, about 120 grains (8 Gm), pentobarbital or its sodium salt from 60 to 90 grains, dial, 115 grains (7.4 Gm), pentothal sodium (sodium ethyl [1 methyl butyl] thiobarbiturate) intravenously, 38 grains (0.25 Gm). These doses (except that of pentothal) are considerably larger than the average ones known to prove fatal in barbiturate poisoning. The dividing line between fatal and nonfatal doses of barbiturates in human poisoning is, however, too broad to be of use in judging the dose in individual cases. Since this group of picrotoxin-treated patients is composed of isolated instances of recovery from very large doses, it seemed more appropriate to compare their doses with the very large doses from which patients have recovered without picrotoxin (see table). The study of the literature has not been exhaustive but a sufficient number of cases of severe poisoning with large doses of barbiturates has been found to serve the purpose. While it is not possible to match treated cases with identical cases in the group not treated with picrotoxin, the data presented in the table suffice to indicate that patients may recover, with the prevailing forms of supportive treatment, from doses of barbiturates within the general range of those in which picrotoxin was held responsible for the survival.

Some of the individual cases merit special consideration. Lundy<sup>10</sup> gave as much as 50 mg of sodium amytal per kilo gram of body weight by intravenous injection for surgical anesthesia. He cited one case in which a total dose of 45 grains (44 mg per kilogram) was given in this way without untoward effects, the patient regaining consciousness on the third day. He cited another case in which a child received 50 mg per kilogram intravenously and had recovered sufficiently to be able to speak twelve hours later. Lundy classifies doses as high as 100 grains (6.5 Gm) of sodium amytal by intravenous injection as those from which patients may occasionally recover (prefatal). Kline, Bigg and Whitney,<sup>11</sup> on the other hand, treated a patient as having amytal poisoning when he consumed 45 grains (3 Gm) of amytal and consid-

<sup>9</sup> These include Wood P M. Five cases reported to the Council on Pharmacy and Chemistry. Kohn R, Platt S and Saltman S. Picrotoxin Barbiturate Antagonism. ered that picrotoxin had played an important role in speeding up the recovery, although from the details of the account it appears that it took about twenty-four hours from the time the drug was taken for the patient to regain consciousness. The largest amount of barbiturate from which a patient recovered was in the case of Purves-Stewart and Wilcox,<sup>12</sup> in the control group. This patient (see the table) consumed the equivalent of more than 700 grains (45 Gm) of barbital and after profound depression recovered in about three and one-half days. Reference has already been made to a case reported by Roventime<sup>8</sup> in which the patient died on the eighth day after 500 grains of barbital sodium, although he was treated vigorously with picrotoxin receiving a total of 2,134 mg.

#### SYMPTOMS OF POISONING

In judging the value of picrotoxin, authors have placed considerable emphasis on the severity of the symptoms of poisoning at the time the treatment was started. There appears to be, however, no single symptom or combination of symptoms short of circulatory or respiratory paralysis, which, in barbiturate poisoning, would indicate a fatal outcome with certainty. The accounts of the symptoms and signs in the picrotoxin-treated cases are indistinguishable from those in the control group. In animal experiments, average fatal doses of barbiturates cause deep narcosis, loss of all reflexes, fall or rise in temperature and extreme grades of vascular and respiratory depression, among these, two animals in which these symptoms may be entirely indistinguishable may take opposing courses, the one going on to recovery and the other to death. The same applies to human cases. Profound respiratory depression, cyanosis, extremely low blood pressure and pulmonary edema have been stressed in some of the clinical cases as indications that the outcome would have been fatal had it not been for the picrotoxin. Hering<sup>13</sup> in 1922 reported a case of poisoning with 75 grains (5 Gm) of phenobarbital in which there was deep narcosis with loss of reflexes, miosis, cardiac weakness, fall of blood pressure, hypothermia and Cheyne-Stokes respiration. Treated with stimulants (kind not stated), warmth and atropine, the patient made an uneventful recovery and was discharged from the hospital within twenty-four hours. Some of the most menacing circulatory and respiratory symptoms (cyanosis, pulmonary edema) in barbiturate poisoning are due in part to mechanical obstruction to respiration by mucus or the relaxed tongue. Attention to these factors and artificial respiration may bring about a reversal of the trend in what at first seems like a hopeless case. Such was the situation in one of the cases<sup>14</sup> in the table in which the patient had regained consciousness eight hours after 86 grains (5.6 Gm) of amytal had been taken although no picrotoxin or other powerful stimulants had been used. Such treatment has also been applied in the cases in which picrotoxin was employed.

#### SPEED OF RECOVERY

Bleckwenn, Masten and Tatum<sup>15</sup> reported that they had made controlled observations in several clinical cases of barbiturate poisoning, from which they concluded that picrotoxin is more effective than other drugs in accelerating recovery from hypnosis and narcosis. The details are not given in the report. In Roventime's<sup>8</sup> report from three to forty-eight hours elapsed after the picrotoxin treatment was started before the patients regained consciousness and treatment was continued for from three to six days. The case reports (see table) were examined for data concerning the duration of narcosis considered as the interval between the time the drug was taken and the time consciousness was restored. In the picrotoxin-treated cases, by and large the approximate interval of unconsciousness ranged from seven hours to six days, in the controls from eight hours to seven days. The control cases were selected for the largest doses of barbiturate rather than

for the shortest duration of unconsciousness, and it is not improbable that instances with shorter periods of unconsciousness in untreated cases exist. It is not necessary to point out here the shortcomings of the data which are being compared, since they apply to most problems of clinical poisoning and are well known. The data are presented for what they are worth. Although suggestive instances may be seen, evidence of a conspicuous increase in the speed of recovery in the picrotoxin-treated cases does not emerge from a comparison of picrotoxin-treated cases with comparable control cases of very severe barbiturate poisoning.

#### MORTALITY RATE

The mortality rate in barbiturate poisoning varies greatly. Leschke<sup>16</sup> states that among 131 cases of phenobarbital poisoning in one series there were ten deaths (about 7.6 per cent), and that for barbital poisoning the mortality reached about 25 per cent. Among the twenty-six cases (excluding the fifth fatal case already discussed) of barbiturate poisoning treated with picrotoxin, there were four deaths (15.4 per cent). The numbers are not sufficient for final conclusions regarding the effect of picrotoxin on the mortality rate. This is all there is, however, and as far as it goes the mortality rate does not appear to have been strongly influenced. One author<sup>8</sup> stated he had treated more than thirty-four patients in over two years but did not present a comparison of the mortality in his group with that of the experience in the same hospital prior to the use of picrotoxin. A more satisfactory comparison of mortality rates cannot be made at this time, although it appears that in the five-year period in which picrotoxin has been used, a sufficient number of patients have been treated to provide a better indication of the trend.

#### COMMENT

As matters stand, there seems to be no room for doubt that picrotoxin causes signs of stimulation in human cases of severe barbiturate poisoning. Although there are indications that picrotoxin may enable a patient to survive during barbiturate poisoning that might result fatally with the customary supportive treatment alone, proof that this is so cannot yet be said to have been supplied by the prevailing reports. In the literature there are cases of barbiturate poisoning in which picrotoxin was not used, which are comparable to the picrotoxin-treated cases with respect to the dose of the barbiturate, the severity of the poisoning, the duration of unconsciousness and the mortality rate. An analysis of the objective factors by which treated and control cases can be compared reveals, therefore, no conspicuous advantage in the picrotoxin treatment. However, the experimental basis for the efficacy of picrotoxin in barbiturate poisoning is fairly strong and since the objective criteria are not adequate for a final conclusion, the favorable impressions obtained by various authors in individual cases merit consideration. The cautious use of picrotoxin in barbiturate poisoning would, therefore, seem justifiable in cases which can be carefully studied, with the view that they may supply sufficient accurate data from which the proper place of picrotoxin as an antidote may be established. In addition to the customary supportive measures, the general practice is to use doses of from 1 to 10 mg of picrotoxin by intramuscular or intravenous injection at intervals of from one to thirty minutes until signs of stimulation occur, and to maintain this state by appropriate repetition of similar or smaller doses as long as indicated by the state of depression. Not enough is known to establish a routine technique. Each case requires expert supervision and critical evaluation of signs and symptoms during the course of the treatment as well as continuous observation over periods of many hours or days. The pharmacology of the very large doses of picrotoxin such as are used in this treatment, is for the most part unexplored, such as the rate and mode of elimination, side effects and the influence of disease on its toxicity. There still remains much to be learned, therefore, regarding the behavior of picrotoxin before it can be used with assurance of safety in the liberal doses that appear to be necessary.

## SENILE OSTEOPOROSIS

Protracted mineral starvation may well be the principal cause of disability associated with the general osteoporosis commonly present in elderly persons. The basic dietary requirements for minerals of infants, and to a slightly lesser degree of older children and adolescents, have been established with reasonable accuracy. Little scientific interest has been shown in the problem of vitamin or mineral nutrition for the adult. The theory that protracted deficiencies in basic nutrition resulting from poor dietary habits may impair the health of the adult and contribute to the factors which produce disabilities commonly attributed to "old age" has rarely been postulated. Orthopedic surgeons have long been aware that many older patients show extreme degrees of demineralization of the skeleton as demonstrated by the roentgenogram. Many adults develop this osteoporosis before they are 50 years of age. A still higher percentage show this skeletal deficiency by or before the age of 60 years. Symptoms produced by moderately advanced generalized osteoporosis may be so indefinite that the skeletal demineralization is unrecognized as a cause of the patient's lack of vigor or premature senescence. Ghormley, Sutherland and Pollock<sup>1</sup> indicated recently that an increased number of patients are entering the clinics of the country with severe disability produced by pathologic fractures of vertebral bodies which weakened by the loss of their lime salts, were not able to withstand the stresses and strains of the ordinary day's activity.

Gradual demineralization of the skeleton over a period of many years may result in pathologic changes in the kidneys or other vital organs and hence affect unfavorably the general health of the patient. It is sometimes forgotten that the bones are alive, that there is a constant interchange of the mineral salts in the bones of all living vertebrates. Generalized osteoporosis in the adult can be explained only on a basis

of chronic or intermittent negative mineral balance over a period of many years.

Maxwell<sup>2</sup> has shown that acute calcium-vitamin D starvation in the adult is the etiologic factor in osteomalacia. Generalized osteoporosis, which produces varying degrees of disability in the aged, may therefore well be merely a chronic, insidious and often subclinical form of osteomalacia. Some evidence has been offered which indicates that adults who live in civilized countries and who eat foods that are specially prepared and refined may not have in their diet the basic requirements of calcium or of vitamin D.

Among the possible explanations of what appears to be a population-wide progressive demineralization without the appearances of a true osteomalacia are first, and most likely, an inadequate amount of calcium in the diet of the average adult. Bernheim<sup>3</sup> has contributed evidence to show that the average adult requires about 0.7 Gm of calcium in the diet daily in order to maintain the mineral balance and she has further indicated that the diet of civilized persons constantly or intermittently lacks that amount of this mineral. Second, the diet of some adults does not contain a sufficient amount of vitamin D to make available most effectively the calcium salts that are present in the food intake. Third, as the patient grows older his ability to absorb mineral salts from the intestinal tract becomes less. This increasing tendency to reject these lime salts may be due to the previously mentioned deficiency of vitamin D in the diet.

Bussabarger, Freeman and Ivy<sup>4</sup> have shown the great importance of the gastric function in promoting normal mineral metabolism. They demonstrated gross skeletal deficiencies in puppies following gastric resection. A gradual decrease in the hydrochloric acid content of the gastric juices of older persons may result in poor absorption of calcium salts and hence constitute one factor in the production of generalized osteoporosis.

The problem of adult nutrition is a challenge to physicians and nutritionists. Complete studies of mineral metabolism should be made on normal or average persons in different age groups. Such studies may reveal that any one of three or more conditions, or a combination of all these factors, in addition to the known effect of endocrine dysfunctions, may be responsible for the protracted or intermittent negative phosphorus-calcium balance leading to skeletal demineralization. Varying degrees of morbidity which we have been accustomed to accept as an inevitable accompaniment of advancing years and have made too little effort to understand or prevent may thus be explained.

### "WE ARE ADVERTISED BY OUR LOVING FRIENDS"

The illegitimate, unethical and peculiar forces which have been arrayed against the advancement of scientific medicine for a quarter of a century seem suddenly to have felt a new stimulus. Like a snarling, vagrant yapping pack at the heels of some great mastiff they cry today to the public the wails of their envy and their discontent. Thus they believe is their long awaited opportunity to destroy the American Medical Association. Almost since the day when the propaganda leading to the indictment of the Association began to appear, the radio, the mails and the commercialized press have occasionally carried this material. Now comes an editorial by Bernarr Macfadden, publisher of *Liberty*, in the current issue of that publication. Says Mr. Macfadden, "doctors—whether they be allopaths, homeopaths or any other kind of 'paths'—after having spent from six to ten years studying their profession, should be guaranteed a decent living by the government. Capable doctors of all kinds should be paid by the government." Indeed, he proposes a competition between all sorts of peculiar healers with regular physicians each having certain sections of the community assigned to them, the mortality and health records of such communities being compared year by year and prizes being offered to the quacks who develop the best records. Moreover, Mr. Macfadden feels that many of the measures for the cure of disease which he has promoted in the past have not had a suitable trial. He wants to cure syphilis by fasting followed by an exclusive milk diet. He wants to cure gonorrhea with water treatments. He wants to replace drugs with artificial fever and apparently thinks an exclusive grape diet will cure cancer.

Perhaps some of the forces within the practice of medicine who have been doing their utmost to disrupt medical organization in recent years will welcome this ally to their cause. Yet if this is not sufficient we offer Dr. John R. Binkley, once of Kansas, now of Arkansas, whose suave tones pervade the midnight atmosphere, reviling the American Medical Association and welcoming with glee the attacks that are being made on it, for it has hindered him in his exploits.

And if Dr. Binkley is not sufficient there is Mr. Norman Baker, who also pollutes the nocturnal air. And if Mr. Baker is insufficient, there is the Medical Section of the Communist Party, which recently issued a manifesto in Philadelphia urging all communists to support the Committee of 430 and to demand salaries for all physicians who have given freely of their service in the past to public institutions and for the care of the indigent sick. Then comes the *West Coast Druggist*, hailing with happiness the experiments recently announced by the Vicks Company, which studied the effects of Va-tro-nol and Vapo-Rub (as reported elsewhere in this issue) on 17,357 volunteers, of whom

several thousand were school children—and "without the sanction of the American Medical Association."

It is a strange assemblage of allies that the times have developed. There is evidence that Henry J. Schireson, plastic surgeon, once of Chicago, is giving aid and comfort to Mr. Morris A. Bealle, editor of *Plain Talk* and now promoter of a scandalous volume entitled "Medical Mussolini."

As the campfires are lighted appear the tents of the makers of innumerable nostrums and panaceas, of many cosmetics promoted with false and fraudulent claims, of strange glandular mixtures and vitamin capsules—all united to batter at the walls within which honest medicine has been reared and nurtured. Now the American people can observe the nature of those who are endeavoring to disrupt, destroy and ruin the standards of scientific medicine. Under a free American government our profession has reached a peak never before reached in any other country—a peak which scientific medicine proudly inhabits and which it will defend to its utmost. In the end, science and truth and honesty and ethics must prevail.

### CLINICAL LABORATORIES AND THE AMERICAN CHEMICAL SOCIETY

In the Organization Section of *THE JOURNAL* this week is an abstract together with some comments on a broadside from the American Chemical Society relative to the work of clinical laboratories. This ill tempered pronouncement has furnished the public with the unedifying spectacle of one professional society of high standing accusing another body of attempting to procure a monopoly. Since the question concerns what is principally a commercial problem ancillary to the practice of medicine, no one involved—either accuser or accused—can benefit in the eyes of the public by the methods employed in the attack.

In essence, the American Chemical Society maintains that the American Medical Association is attempting to obtain a monopoly in the field of diagnostic laboratory work by approving only those clinical laboratories which are directed by one holding an M.D. degree and by urging physicians to patronize only such laboratories. There is no allegation that the American Medical Association discourages the employment of qualified chemists, bacteriologists and others in some of the work of those laboratories. The complaint and the charge of monopoly by this society rest on the alleged advice given by the Council on Medical Education and Hospitals of the American Medical Association that the directors of laboratories doing tests for practicing physicians involving as they must clinical diagnosis should be physicians especially qualified in this field, and that therefore chemists would be discouraged from forming and directing such laboratories.

The interest of the American Medical Association in clinical laboratories as such is based on the desire that patients, through their physicians, receive the best and most authoritative supplementary diagnostic assistance which the clinical laboratory can supply. In this it is well recognized that only one well trained and qualified in chemistry can suitably carry through certain tests now frequently required of the clinical laboratory although no standards for chemists doing this work have been devised or enforced by the Chemical Society. A similar situation exists with regard to other special tests often required of such laboratories. In the pursuit of this problem and in its role as adviser, the Council on Medical Education and Hospitals found it necessary to discontinue approving clinical laboratories principally because the personnel and often the location changed too rapidly. It was therefore felt that the interests of the profession in this respect could be best served by approving the qualifications of clinical pathologists engaged in this type of work. Such qualifications were less likely to be suddenly changed and such action lay in a field more immediately related to the other activities of the American Medical Association. None of these reasons for the position of the American Medical Association in this matter were referred to in the broadside that was released by the American Chemical Society.

The true nature of the problem is important and should receive more detailed study. The first prerequisite would seem to be a definition of the term clinical laboratory. Further, it will be necessary to determine exactly how far an independent laboratory worker is acting as a consultant in clinical practice. The part which the clinical laboratory plays in suggesting diagnosis, prognosis or treatment must determine the decision whether or not the laboratory is actually engaged in the practice of medicine and must therefore be under the direct supervision of one who is licensed so to practice. Certainly no one can deny that many such institutions do actually function in this manner. Thus it is claimed by the State Board of Medical Education and Licensure of the Commonwealth of Pennsylvania (and this seems undoubtedly to have been the precipitating factor in the action of the American Chemical Society) that clinical laboratories in that state were actually engaged in a phase of the practice of medicine and therefore could legally be directed only by a licensed physician. If the law in Pennsylvania is unwise or its interpretation is mistaken, correction should be made. The controversy between the State Board of Medical Education and Licensure of the Commonwealth of Pennsylvania and the American Chemical Society served no doubt as the precipitating factor in this attempt of the American Chemical Society to becloud the issue by attacking the American Medical Association and shrieking "Monopoly."

## Current Comment

### BLOOD PLATELETS IN ALLERGY

In a preliminary study recently reported by Thiberge,<sup>1</sup> blood platelet counts were made on twenty-seven patients with various types of allergic disorders both during an attack and in convalescence. In the five cases of hay fever there was an average rise in the platelet count of 55,600 after subsidence of the attack, in the fifteen cases of asthma there was an average rise of about 17,000 in the platelet count and, in the three cases which failed to show a rise, one was complicated with sinusitis and two with tuberculosis. The platelet counts in the six cases of cutaneous allergy during and after an attack were, however, variable. The author reaches the tentative conclusion that improvement in uncomplicated asthma and hay fever is always indicated by a rise in the number of platelets.

### MITOTIC RHYTHM IN HUMAN TISSUES

The rate of cell division in normal human tissues shows a well defined diurnal rhythm, which presumably has a bearing on numerous clinical phenomena. Botanists have long recognized that the rate of normal cell division undergoes rhythmic variations in plants.<sup>1</sup> A similar rhythm has been recently demonstrated in the thyroid glands and other internal tissues of smaller laboratory animals.<sup>2</sup> In order to determine whether or not the same rhythm exists in human tissues, Cooper and Schiff,<sup>3</sup> of the Barnard Free Skin and Cancer Hospital, St. Louis, studied the skins of eight day infants removed at routine circumcision. The specimens were obtained at various hours throughout the day and night and were placed immediately in 1 per cent acetic acid. After twenty-four hour maceration in this fluid it was possible to separate completely the layer of epidermis from the underlying dermis. These epidermal specimens were stained with hematoxylin, dehydrated, cleared, mounted and studied under the oil immersion lens. Five thousand epidermal cells were counted in each specimen and the number of mitotic figures recorded. In six specimens removed between 7:30 and 10:30 a.m. the number of mitotic cells varied from seven to sixteen per specimen, an average of twelve mitotic figures to 5,000 cells. In six night circumcisions (8:45 p.m. to 12:45 a.m.) the mitotic number varied from twenty-three to thirty-five per specimen, an average of twenty-seven mitotic cells in 5,000. The average night rate of epidermal cell division therefore is 2.25 times the forenoon average in eight day infants. Whether or not a similar rhythmic periodicity of proliferation is shown by cancer cells is now under investigation, as well as a study of the effects of various hormones and therapeutic agents on both rate and rhythm.

# ORGANIZATION SECTION

## AMERICAN MEDICAL ASSOCIATION COMMITTEE CONFERS WITH INTERDEPARTMENTAL COMMITTEE AND THE PRESIDENT

On Sunday January 15 the special committee of the House of Delegates of the American Medical Association conferred in Washington with the Interdepartmental Committee to Coordinate the Health and Welfare Activities of the United States Government. Those present included Drs. Vest, Carey, Donaldson, Luce, Rankin, Sondern, West and Abell, with the addition of Dr. Woodward. The Interdepartmental Committee was represented by Chairman Josephine Roche, Mr. Altmeyer, Dr. Parran, Mr. Perrott and the members of the Technical Committee on Medical Care, Drs. Martha Elliott, J. W. Mountin and C. E. Waller and Messrs. I. S. Falk and G. H. J. Perrott. Opportunity was given for extended discussion of the various recommendations in the National Health Program. The committee representing the American Medical Association

presented the point of view of the House of Delegates. It was apparent that the Technical Committee had not receded in its attitude in favor of compulsory sickness insurance.

On Monday January 16 the special committee of the House of Delegates, together with Miss Roche and Dr. Parran, were received by the President. Dr. Abell briefly stated the attitude of the American Medical Association and repeated the offer that had been made by the American Medical Association to aid in working out the problem.

Obviously the conferences with the Interdepartmental Committee in no wise changed its attitude. Its report, as sent to Congress by the President, is in all particulars approximately the same as presented to the National Health Conference in July 1938.

## THE MEDICAL CARE OF THE POOR AND UNEMPLOYED

CHARLES V. CRASTER, M.D., D.P.H.

Health Officer  
NEWARK, N. J.

The city of Newark may be taken as a typical setup for the medical care of the poor by the municipal government. For the last fifty years and more this city has maintained a free dispensary service with a staff of district physicians for visiting the bedridden poor. The cost of this service was borne by the health department and its supervision by means of a dispensary medical board cooperating with the health officer.

Medical services are maintained for the poor families on the relief rolls but also include service for families who, by reason of low wages, are unable to pay for medical, surgical or hospital care.

### TYPE OF MEDICAL SERVICES

The city dispensary provides all types of medical and surgical services as well as dental facilities for adults and children. The medical staff is composed of volunteer physicians together with part-time physicians who receive an annual salary of \$600 for six hours of work a week. The usual plan is for three days of service a week or two hours a day. It was long ago found to be impossible to maintain regular efficient clinics without paid physicians.

The medical staff is supervised by a medical board which makes all recommendations for the type of service rendered. Clinics for all types of medical service are carried on including medical, surgical, pediatric, genito-urinary, gynecologic, dermatologic, proctologic, orthopedic, hernia, antepartum, cardiac, neuropsychiatric, metabolic, gastro-enterologic, varicose vein, dental, venereal disease, asthma, hay fever, tuberculosis, pneumothorax and occupational clinics.

Besides the routine medical services there has evolved a need for certain expensive medications. For instance, the dispensary gives free insulin for indigent diabetic patients. The cost of this medication alone amounts

to more than \$9,000 a year. Free distribution of cod liver oil for undernourished children has also been added. The cost of this averages \$5,000 a year.

The city is thus faced with a demand for medical services which would under more normal conditions of prosperity, be borne by the individual wage earner to the advantage of the rank and file of the medical and dental profession. The incomes of physicians and dentists have in many cases shrunk to the vanishing point because a large group of the public has no money to pay a physician, especially at the old scale of pay, although the need for medical care remains the same.

### THE SICK IN THE HOME

The indigent sick in the home are taken care of by a staff of twelve district physicians who are assigned to specified districts in the city and each receives a salary of \$1,000 a year, with an allowance of \$25 for each emergency obstetric patient they may take care of. There is also a night physician who works from the City Hospital and who responds to night calls between 11 p. m. and 8 a. m. The work of the district physician is supervised by a medical receiving officer at \$2,500 a year.

### THE PHYSICIAN'S ATTITUDE

The physician apparently realizes that some form of free medical service is inevitable and necessary for the indigent poor. What he is quite sure of is that the physician giving such service under municipal government salaries is usually inadequately paid to such a degree that the quality of the service is below the standard maintained for paid services to the private patient.

At the present time, with social security in the offing, some form of medical relief must be considered not only for the poor and the employed poor but also for all employees whose wages are low.

The physician's opinion with regard to how this service may be built up within the framework of ethical medicine must be given its due consideration.

#### THE MEDICAL ASSOCIATION'S ATTITUDE

At the discussion on medical insurance plans for relief before the House of Delegates of the American Medical Association in Chicago, Nov. 18, 1932, Dr. A. R. Mitchell declared on behalf of the Board of Trustees that in any plan for organized medical relief "the first dictum shall be free choice of hospitals and free choice of physicians. The second dictum is that

TABLE 1—Families and Individuals on Relief

Total estimated population of Newark, from 442,000 to 458,000		
December	Families on Relief	Persons on Relief
1930	5,484	24,129
1931	7,180	30,592
1932	14,331	58,564
1933	21,902	90,989
1934	14,393	61,094
1935 (FRA)	18,885	82,700
1936	12,488	37,622
1937	12,676	37,190
1938	16,756	19,171

the prevailing charge shall be paid by the insurance company or the group of doctors who are going to be responsible for the administration of this service. The next dictum is that there shall be no profit to the organization, that the profit shall consist of the fee to the doctor and the service to the participants in the plan." So much for the ethics of any plan in which organized medicine is concerned. The present position of the American Medical Association is fundamentally the same as the opinion outlined in 1932.

#### THE IMMENSITY OF THE MEDICAL RELIEF PROBLEM

Some idea of the army of persons requiring medical care who are at present on relief rolls of municipalities may be envisaged by the figures for Newark. Table 1 shows the number of families and persons on relief in Newark during the nine years 1930-1938.

During these nine years the demand for medical care of the indigent poor, as well as the poor not on the relief rolls but unable to pay for medical services, has been an increasing load on the municipality. Table 2 shows the number of treatments given in the clinics of the city dispensary, the number of free prescriptions filled and the number of calls made by the district physicians in 1929 and 1930 compared with the years 1935, 1936 and 1937.

The curtailment of family incomes and the greatly increased number of indigent poor have brought about since 1929 greater demands for free medical and surgical services. Prior to 1929 the city dispensary treatments averaged slightly less than 100,000 a year, with an equal number of prescriptions dispensed. The calls for medical service in the homes increased from 5,370 visits in 1929 to 18,242 in 1937, more than a 200 per cent increase in eight years.

#### THE COST OF MEDICAL CARE IN NEWARK

Table 3 shows the annual cost of medical care in Newark for 1929 and 1930 compared with 1935-1937.

#### THE COMBINED COST OF MEDICAL CARE

In addition to the amount of \$178,000 spent for the ambulant home medical care in 1937 there were of course additional items of hospital care. These are shown in table 4.

This total amount of course does not include the cost of free medical and surgical care rendered by the private hospitals and physicians of the city. The combined tax paid medical bill amounts to 5 2/3 per cent of the combined city operating expense for all purposes and a per capita cost of \$3.66 for all the residents of Newark. There are undoubtedly many other tax items for medical care which are difficult to compile, for instance public school dental clinics and infirmaries in the jail and other institutions. In addition to the tax paid medical care, the Community Chest also gives approximately \$200,000 a year to charity hospitals, or an additional 43 cents per capita.

Up to April 11, 1933, the medical care of the poor, including those on the relief rolls, was entirely carried on by the health department clinics. From that date until April 16, 1936, this medical service for actual relief cases was administered by the Federal Emergency Relief Administration (ERA) with a local staff unit setup. All applicants for medical relief during this period who applied for treatment to the city dispensary, both ambulant and at home who were on the relief rolls were referred to the ERA, the exceptions being patients with tuberculosis or a venereal disease as well as many special patients who needed light treatment and the like.

It is remarkable to note therefore, that in spite of the absence of most of those on relief from our clinics there was a continuous demand for free medical service in the dispensary and for district calls.

Apparently between these dates the treatment load carried by the dispensary was changed little if any, and only in one year (1935) was there any decrease in the calls for the visiting physicians. Who are these people, then, who crowd the free clinics and yet are not the indigent poor? The answer is contained in the report of our investigation department. All persons who apply for free medical treatment are carefully questioned by the admitting staff, and whenever doubts exist or treatment and medication is more than trivial the applicant is checked up by "follow-up investigation." In few of these cases can fraud be brought home to the applicant. The majority are of the low wage group, persons unable to pay for any form of medical care at existing rates. In this group we had

TABLE 2—Increase of Demand for Medical Care in Nine Years

Year	Free Treatments	Free Prescriptions	District Physician Calls
1929	110,721	114,557	5,370
1930	139,816	168,956	9,763
1935	281,615	158,616	4,819
1936	274,066	92,980	10,340
1937	268,947	116,940	18,242

to place all workers employed under WPA projects, whose wage scale is so manifestly low as to make impossible the ordinary payment for medical care.

#### MEDICAL RELIEF UNDER THE ERA

From April 12, 1933, to April 16, 1936, as stated, medical care of the indigent poor was under the Federal Emergency Relief Administration.

Under this plan all physicians wishing to volunteer for relief service were asked to register their names with a medical board appointed from the county medical society. This board submitted the names of such physicians to the ERA and also advised on the medical problems arising from this service. The scale of payment adopted and approved by the medical societies

was a flat rate of \$2 for a home call and \$1 for an office visit. The patients had a free choice of physician and there were at first no restrictions on the number of calls made on any one patient. A fee of \$25 was allowed for all maternity patients delivered in the home. This fee included all antepartum and postpartum care.

In the beginning there was no limit as to the amount of fees collected by any one physician under this plan.

TABLE 3—*Annual Cost of Medical Care in Newark*

Year	Cost of City Dispensary	Pay for District Physicians
1929	\$ 61 000	\$ 6 546
1930	81 000	7 600
1935	138 000	6 800
1936	163 000	11 000
1937	160 000	18 000*

\* District physicians were paid for ten months at \$1 500 a year by the Outdoor Poor Relief Department instead of \$1 000 a year in the health department. The cost figures for 1937 approximate about 50 cents per clinic treatment and 25 cents for each prescription. The cost of the calls made by district physicians would average approximately \$1 a visit.

TABLE 4—*Additional Items of Hospital Care*

City dispensary and district physicians (1937)	\$ 178 000
City hospital 750 beds (annually)	960 000
Convalescent hospital 155 beds (annually)	86 000
Free beds in private hospitals (paid by city annually)	10 000
County isolation hospitals 400 beds Newark pays 55% amounting to	175 000
County Tuberculosis hospital at Verona 447 beds Newark pays 55% amounting to	275 000
Total medical care paid by city taxes	\$1 687 000

When the costs of this service began to mount, however, a limit of \$200 was established for the earnings of any one physician in one month. All bills had to be submitted to the county office of the ERA on or before the 10th of the following month.

In order to obtain the services of a physician, the patient or any member of the family was required to obtain an authorization from the local relief office. This authorization was limited to not more than three visits. If more than three visits were required, further authorization slips were needed.

For emergency calls after office hours, the physician was supplied with a book of blank emergency authorization slips. This was particularly used for night calls. Medical prescriptions were made out on forms supplied to the physician and were compounded by pharmacists, the cost being paid by the ERA.

#### THE FRAMEWORK OF MEDICAL SERVICE UNDER THE ERA

The plan for medical service under the state emergency Relief Administration apparently met the conditions laid down by the American Medical Association. There was freedom of choice of physicians, and there was a flat fee of \$2 a visit and \$1 for an office call which was agreed on by the county medical society. The quality of medical services rendered and the various problems that arose thereto were supervised by a medical committee appointed by the county medical society. Although this service was at first limited to families on the relief rolls, it was broadened later to include families of the low wage groups.

It can be said in favor of this plan that there was every incentive to give medical service of a high standard, for the reverse would mean a loss of patients to the physician so complained of.

Apparently the service offered, particularly the home visiting, was taken advantage of by a greater number of the poor than was that offered by the city under

the paid district physician plan, although the demand for the city service was little diminished during the ERA period of medical relief. The principal difference between these two services was that of the cost, that for the ERA plan being much in excess of the cost of the dispensary and city physicians as maintained by the municipality.

#### THE COST OF THE STATE ERA PLAN FOR MEDICAL CARE IN NEWARK

Table 5 is a summary of the cost of medical care under the Emergency Relief Administration for the two and one-fourth years, from January 1934 up to April 1936, in the city of Newark. For the year 1933 the cost figures were incomplete.

For 1936, ERA figures were separated into services of the physician and the dental and nursing services. Since no separation was made for 1934 and 1935, table 5 was made by using the same proportions as for 1936. The total costs for medical care under the city plan and the ERA setup are not comparable, since the services rendered were apparently for two different groups of the poor. The ERA was for the indigent poor or persons on the relief rolls and the city dispensary and district physicians were for the low wage family not essentially indigent. The cost for these two services for the year 1935 are given in table 6.

Had the prevailing rate for medical care as in force for the state emergency relief been applied to the city service, the cost would have been \$370,561, as summarized in table 7 for the year 1935, instead of \$144,800.

#### SUMMARY

1 The low wage family naturally demands free medical service to the same degree as that given the indigent poor yet resents being placed in the indigent class or having to apply for medical service through the relief agencies.

2 Shall municipalities contemplate building more free dispensaries with larger staffs of visiting physicians on salaries or on a fee basis?

TABLE 5—*Cost of Medical Care Under Emergency Relief Administration*

Year	Total Medical Services	Dental and Nursing Services	Physician
1934	\$150 018 08	\$30 018 08	\$120 000 00
1935	259 521 47	51 521 47	208 000 00
1936 (1st quarter)	49 088 50	9 931 00	39 157 50

TABLE 6—*Cost of the Two Services for Medical Care*

City dispensary and district physicians	\$144 800 00
State emergency relief medical care	259 521 47
Total cost	\$404 321 47

3 For fifty years the city of Newark has maintained a free dispensary and free district physician service.

4 Expensive medication is supplied, for example insulin for indigent diabetic patients at \$9,000 a year.

5 The present setup in Newark does not meet the standards established by the American Medical Association as to free choice of physician by the patient or as to the fee for physicians.

6 The extent of indigence in Newark shows 49,371 persons on relief in 1938 (more than one person in every ten). If WPA workers and the low wage group and their families are added, the number eligible for free medical care approximates one in four.

7 In 1937, 268,947 treatments and 116,940 prescriptions were given at the Newark City Dispensary and 18,242 physician calls were made by district physicians, as compared with 110,721 treatments and 5,370 home visits in 1929. Prior to 1929 the city dispensary treatments averaged less than 100,000 yearly.

8 The cost of medical care increased 100 per cent between 1929 and 1937 in the city of Newark. The total tax paid cost for medical care, hospital and ambulatory, in the city of Newark is now \$1,687,000 a year, added to another \$200,000 for hospitals given by the Community Chest.

9 The cost of the health department dispensary and medical care in the home amounts to \$178,000 a year. Emergency relief during 1933-1936 did not reduce to any great extent the medical cost to the health department.

TABLE 7—Hypothetic Cost of City Service Based on Charges for State Emergency Relief Medical Care

281 615 dispensary clinic visits at \$1	281 615
158 616 prescriptions filled at 50 cents	79 308
4 819 physician calls at \$2	9 638
	\$ 70 561

10 The emergency relief plan was satisfactory in providing free choice of physicians and a flat medical fee agreeable to the medical societies. The cost of medical dental and nursing services for 1935 in Newark under the ERA amounted to \$259,521.47. Had the city of Newark medical service been paid for at the same rate as the ERA service, the cost for 1935 would have been \$370,561 instead of \$144,800, the actual cost during that year.

11 The salary of Newark district physicians is \$1,000 annually as compared with a maximum earning capacity of \$2,400 a year under the ERA.

#### CONCLUSION

Under the free dispensary and district physician plan the cost of service is kept at a low figure, the average for a physician call is between 90 cents and a dollar and clinic treatments average 25 cents. This service does not allow any choice of physician, and the quality

of service rendered has a tendency to deterioration. With very few exceptions the reaction to a paid salary is to minimize as far as possible the extent of the service rendered. This can be understood when one considers the excessive calls for medical treatment that are made on salaried physicians at certain seasons of the year. The "off" period, when service calls are infrequent, are too soon forgotten by the salaried man.

Another serious objection to the salaried physician is the attitude of the public. The term "poor doctor" has not been forgotten, and frequently discourtesy, unfriendliness and actual hostility of the patient's family awaits the visit of the district physician. This attitude is not so prevalent when the physician demands and receives a fee for each attendance, which is much more in conformity with medical practice.

The free choice of physician is in my opinion essential for a proper relationship between the doctor and the patient. Whatever framework is set up for the medical care of the employed and the unemployed, it should meet the following conditions:

1. A service of reasonable cost to the community in which the physician should be willing to receive a fair standard fee for his services.

2. Free choice of physician.

3. Creation of a division of medical care in all health departments with an advisory committee appointed by the local county medical society.

4. All dispensary services to be standardized, with physicians paid for actual services instead of annual salaries.

5. A medical advisory board appointed by the county medical society to advise and correlate dispensary services.

6. A pharmaceutical board appointed by the state pharmaceutical society to standardize and correlate the cost of medical prescriptions given to private pharmacies.

7. The creation of a position of director of medical care who could be a physician or layman of exceptional ability to supervise and coordinate all the various branches and specialties of medical care and to advise on problems affecting hospital care.

### THREE TRIBUTES

Eloquent testimony to the places which physicians hold in the hearts of the people of this country was presented recently in three notes published in local newspapers as editorial comment on the deaths of physicians. The Jackson, Miss., *News* says of Dr. John K. Bullock:

The age of 39 is quite too young for a good and useful man to die, but such was the cruel fate of Dr. John K. Bullock, one of Jackson's ablest physicians.

Dr. Bullock loved little children, and it was this love that prompted him to select pediatrics—child diseases—as his specialty in the field of medicine. Lots of little folks in this state cried bitterly when they heard of his death for he had straightened their crippled limbs, put them erect on their feet, and thus gave them a fair fighting chance in life's battle. It was Dr. Bullock's fondest hope and dream to some day establish a hospital for crippled children in Jackson where little ones afflicted with malformations could obtain free treatment.

The friendly, lovable, kind-hearted nature of Dr. Bullock drew people irresistibly to him and inspired confidence in his medical skill. He had built up a splendid practice that extended

to many other places in the state and was earning a reputation for orthopedic surgery akin to that achieved in world medicine by Dr. Willis Campbell in his great clinic at Memphis.

In Wilmington, N. C., the *News* writes of Dr. Julius Arthur Doshier:

Dr. Doshier of Southport, who died yesterday, was one of the leading surgeons of the South if not of the entire country, and had he elected to remove to a large center his reputation would have been world wide.

But like many of the great men of his profession, Dr. Doshier preferred the neighborly friendliness of his own people as an atmosphere for his work, and while this decision denied him fame and perhaps fortune, it did not detract from his real greatness.

And in Bristol, R. I., the *Phoenix* said, in part, concerning Dr. Alfred Mitchell Merriman:

Was there any one in Bristol who did not feel a sense of personal loss when they heard over the radio Monday morning the word that Dr. Merriman had died Sunday night in the Jane Brown Hospital? He had gone for a two weeks rest

and then his heart gave out and he was taken to the hospital in Providence, where he lived only two weeks more.

What can we do without him? He was our mainstay, our rock of defense in every trouble. In every accident, every sudden illness, the first thought was to send for Dr. Merriman and he never failed us.

When he made his last evening call he would say to the anxious family, "Don't hesitate to send for me if you think you need me in the night," and when the telephone rang he appeared in no time with his hypodermic syringe. To his paralysis patient who lay helpless in bed for weary months his last call was a gay good-bye and the parting word, "Remember, I am coming to take you for a drive next week."

It is not only his skill as a physician and surgeon that we remember, but his generosity and kindness.

He was, moreover, a most generous citizen, giving to every public cause. We all know of his work with the Y M C A, the Soldiers' Home and countless other causes. The Merriman house was ever the center of hospitality.

The Doctor was a great lover of music and the Bristol Train of Artillery, of which he was Commanding Officer, was his delight. Many a night, after a long day's work and a busy evening with office calls, he would dash up to the Armory to hear his band practice. Six years ago, in the time of the depression, he realized that the morale of the town was running low. He therefore thought of community concerts in the open air.

We were his guests. He paid all the expenses.

Dr. Merriman was a splendid man. He was our friend—our "Beloved Physician."

## THE PRESIDENT'S HEALTH PROGRAM

[The Providence, R. I. Journal, Jan. 24, 1939]

We note that President Roosevelt, in submitting his proposal for a permanent system of federal-state compulsory health insurance, asked Congress to give the program its "careful study." This is putting it extremely mildly, since the program involves so many vital economic and professional issues that Congress cannot expect to act wisely without the most searching consideration of every phase of the plan over a period long enough to inform the public thoroughly.

This is no matter to undertake quickly or emotionally, despite the fact that there is an admitted lack of adequate medical care for a large portion of the population in some sections of the country. Yet up to the moment it has been handled in just that manner. The President's interdepartmental committee's report and recommendations, which he transmitted with his message, is based upon the theory that only the United States government, with the cooperation of the states, can meet those needs.

The American Medical Association believes, as the President and his committee do, that there is a serious need for an extension of medical services on a basis that will enable all groups to possess them at a cost that is not too burdensome. The Association now acknowledges that its problem is to make American medical standards, which are the highest in the world, available to all the people, and it is facing it, not without some success, here and there. In Rhode Island, for example, the profession is presently seeking enabling legislation which will permit the organization of group hospital service, which is akin, perhaps preparatory, to the formation of some group medical service on a voluntary basis.

The President informs Congress that the committee's recommendations are based upon reports prepared by its technical experts, and that both recommendations and reports were discussed at the National Health Conference held in Washington last June under government aegis. He says that at that conference attended by many representatives of the medical profession and local health departments, there was agreement on these two fundamental points: first, the lack of adequate medical care for many groups, and, second, the failure to make full application of the growing powers of medical science to prevent or control disease disability.

This is dissembling, since it fails to take account of the fact that the Health Conference was wholly a governmental affair; its program prepared long before it was held. Since, too, it makes no mention of the fact that the medical profession after agreeing to the two fundamental points disagreed wholly with the major proposal, which was to set up a system of federal-state insurance.

That disagreement was based on the belief that such a system would mean the complete socialization of medicine, controlled and directed by the government with concomitant losses in the lowering of medical standards and the evils that flow from political control. That still is the American Medical Association's position, just as it is of not a small part of the nation's population.

The President declares that no elaborate extension of the federal government's health service is planned. The program is to be administered by the states and localities, with the aid of federal money (presumably, 50 per cent of the funds). Such a program has obvious advantages, but it has so many disadvantages and presents so many evils that these are likely to destroy the advantages.

Let us assume that administration is to be decentralized on state lines. Does that eliminate the danger of politics or government control? Not at all, for each state must appropriate its share of the funds, and that means both political and social

### EXAMINE BEFORE YOU BUY

From the Providence Journal Jan. 24, 1939

consideration of the problem each year. It means a state department, which must perpetuate itself in office by a steady flow of state and federal funds and that means political maneuvering. If any one doubts this, let him consider the persistency and thoroughness with which county agricultural agents in many of the states play politics today, not only to keep in office, but to make sure that the government's system of crop control paid for by cash benefits is continued.

And of course, it means a considerable measure of control from Washington. It means a new federal bureaucracy, in time no doubt a new department of the government and thus a political instrument of the administration in power.

Consider, too, the cost. The President's plan, in time, will mean an expenditure by the government and the states of \$850,000,000 every year. This is an additional burden on the taxpayers, no matter how the money is raised.

If it is a pay roll tax, about which there seems to be some doubt, it means that the wage earners' purchasing power is to be correspondingly lowered, not only because a portion of his wages is withheld every week but because his employer also must contribute, and that means an increase in costs of production, with further assessments on profits and, therefore, upon the employer's ability to pay his workers.

Such a tax certainly would make the scheme compulsory, and that would constitute compulsory health insurance at its worst. Despite any protestations to the contrary, it would mean the loss of freedom of selection in the matter of medical care.

The state administration ultimately would be forced to engage doctors for the work, and only the poorer and ill equipped

type would be available. That has been the history of compulsory health insurance in nearly every country which has tried it.

It would mean a lowering of medical standards and a weakening of medical science, since the keen competition among private practitioners would be stifled. Medical treatment would be on a political basis, and any such medical practice is bound to become cold and inefficient. And here, again, the individual would suffer.

There are many phases to the issue which the President has raised. They should be considered thoroughly and at length. Let Congress adopt a program so impractical, so unwise, so political as to destroy much of the great progress which science has made in this country.

Extension of medical service to low income groups is one thing. Government domination of medical practice is quite another. By all means, let us all "Stop, Look and Listen" before we commit ourselves to any plan of this sort.

## THE AMERICAN CHEMICAL SOCIETY AND CLINICAL LABORATORIES

In the January 20 issue of *Industrial and Engineering Chemistry News Edition* appears a voluminous discussion over the signature of Charles L. Parsons, secretary of the American Chemical Society, entitled "Chemical Laboratories: A Monopoly Proposed for the Medical Profession." This discussion inspired an article in the *Washington Evening Star* for January 23 headed "Chemical Society Says A. M. A. is seeking Monopoly" and in the *Washington Herald* for the same date headlined "D. C. Chemists Unit Joins in A. M. A. Monopoly Charge." What are the circumstances leading to the publication of this material?

According to *Industrial and Engineering Chemistry* publication was authorized "in order that members of the American Chemical Society may be fully informed, that physicians may have full knowledge of the situation that exists and that material may be available for use in any proposed legislation that may be found necessary to conserve the public health by ensuring that chemical work in clinical laboratories, in public health organizations, in hospitals, and in similar institutions shall be performed by, or under the immediate direction of, an adequately trained chemist or by an individual whose qualifications to practice chemistry are beyond peradventure. The basis of the American Chemical Society's allegations concerning the American Medical Association rests on an alleged violation of the letter and spirit of the report of a joint committee of the American Chemical Society, the American Medical Association and the American Association of Pathologists and Bacteriologists in 1924, on the subject of Clinical Laboratories. This report was adopted by the House of Delegates of the American Medical Association in the same year. The report is adopted follows:

In proposing the following specific recommendations concerning the regulation of clinical laboratories the joint committee of the American Medical Association, the American Chemical Society and the American Association of Pathologists and Bacteriologists wishes to emphasize the importance of encouraging and ensuring the adequate education of every laboratory worker in the fundamental sciences which he applies. A clinical laboratory, as that term is used by the committee, is an institution organized for the practical application of one or more of the fundamental sciences by the use of specialized apparatus, equipment and methods for the purpose of ascertaining the presence, progress and source of disease.

It is the unanimous judgment of the committee:

(1) That it should be illegal for any person not licensed by law so to do as to assume the responsibility of making the diagnosis or of deciding on the progress or source of disease on the basis of any results of a chemical, pathological, serologic, bacteriologic, radiologic or microscopic observation or other laboratory examinations undertaken and that where laws do not now restrict diagnosis or the clinical interpretation of laboratory examinations to licensed classes of medical practitioners laws should be enacted to effect that end.

(2) That any law providing for the licensing of professional workers in laboratories devoted to ascertaining the present progress or source of disease should provide for the examination of members of each profession by competent authorities belonging to the same profession.

(3) That as long as an organization or individual engaged in examinations to ascertain the presence, source or progress of disease refrains from all diagnostic and prognostic interpretation of the results of such laboratory tests as provided for in paragraph 1 any effort to force such

organization or individual to place itself under the direction of a representative of any other profession is to be deprecated.

(4) That the American Chemical Society, the American Medical Association and the American Association of Pathologists and Bacteriologists should cooperate to establish the principles enumerated in the foregoing resolution whenever legislation in this field may be proposed, and that the cooperation of other national bodies should be solicited.

(5) That clinical laboratories be standardized in accordance with the principles laid down in the preceding paragraphs and legislation should be enacted to ensure competent personnel and suitable equipment.

This has been modified only so far as the House of Delegates has adopted subsequent reports of the Council on Medical Education and Hospitals affecting this problem.

The American Chemical Society in this report quotes from reports of the Council on Medical Education and Hospitals at various times as presented in *THE JOURNAL*, such items as appear to be at variance with the report previously mentioned. It calls attention to the fact that for several years the Council on Medical Education and Hospitals published the "Essentials of an Approved Clinical Laboratory" but that in 1929 the list formerly headed "Approved Clinical Laboratories" was changed to read "Pathologists Conducting Approved Clinical Laboratories" and that both lists were limited to laboratories headed by men holding the M.D. degree. Finally the report complains that in 1933 the heading was again changed, this time to "Physicians Specializing in Pathology and Clinical Pathology."

In quoting from statements of the Council on Medical Education and Hospitals as presented in *THE JOURNAL*, the American Chemical Society evidently takes exception to such statements as the following: "Many physicians in the past, not appreciating fully the importance of medical supervision over their work, had patronized lay laboratories. The patient should be given the benefit of the most accurate analysis with regard to the source, nature and progress of the disease. In order that this may be assured, physicians should have their work carried out in laboratories under the supervision of capable physician pathologists." And "Through the activities of nonmedical clinical laboratories the interests of the patient are jeopardized and frequently the true source, nature and progress of the disease are not ascertained." In the report of the Council on Medical Education and Hospitals adopted by the House of Delegates at the annual session in 1932, the following comments and recommendations are made:

"Essentials of an Approved Clinical Laboratory" were adopted by the Council in compliance with instruction received from the House of Delegates in 1923. The rating of laboratories has been found to be in some instances misleading because of changes in personnel. The Council has found it more practical to emphasize the qualifications of the pathologist than of the place in which he works and to this end at its February meeting adopted a statement of the Essentials for the Listing of Physicians Specializing in Clinical Laboratory Work and Pathology.

In the chemical society's report no mention is made of any reason for the recommendations of the Council on Medical Education and Hospitals and one would be led to believe that there were no reasons other than self interest.

Perhaps the acute situation which the American Chemical Society believes has arisen lies in a controversy now going on in Pennsylvania between the Chemical Society and the State Board of Medical Education and Licensure. According to the reprinted letter written by Dr I D Metzger, chairman of the State Board of Medical Education and Licensure, "There has been no law recently passed in respect to clinical laboratories as such specifically. Act 417 passed in 1935 and effective September first of that year provides that all persons doing any medical work that enters into the welfare of patients must be licensed to practice medicine or a branch thereof. Clinical laboratories do enter into the welfare of patients, inasmuch as reports from them are requested and secured by physicians only because of their aid in the diagnosis and treatment of cases. It is obvious, therefore, that all such reports should be made by licensed physicians who may be legally responsible for them." In essence, therefore, the Pennsylvania situation is one which involves the American Chemical Society and the state of Pennsylvania, and it is irrelevant to draw the American Medical Association into the picture. If the law or its interpretation in Pennsylvania is unsatisfactory, this matter should be taken up with the state authorities rather than by any attempt to charge another professional organization with those measures which are purely state enactments.

Further correspondence is quoted between the American Chemical Society and the American Society of Clinical Pathologists. On these issues the American Medical Association has taken no official action. Finally, the report closes with a charge headed 'Monopoly for Physicians Boycott of Nonmedical Directors,' in which the chemical society protests against 'the unsurpassed arrogance of the assumption that the findings of other learned professions, before being accepted by the physician, must be made sacrosanct by the seal of an M.D.' Certainly there is no evidence that any such claim has ever been made.

The report closes with a brief statement on the position of the American Chemical Society, reiterating its readiness to participate with the American Medical Association and other

interested national societies in establishing standards for laboratory directors in accordance with the resolution. The society maintains that "every director of a clinical laboratory should be well educated and thoroughly competent in chemistry, pathology or bacteriology, but that no degree, in itself, is a guaranty of specific knowledge and efficiency in this branch of endeavor."

This lamentable controversy, initiated by a professional society which might well have foreseen the nature of the attendant publicity, can only be deprecated by all who have the interest of the public or of their respective professions at heart. Certainly one might expect from the American Chemical Society more scientific and professional approach to a problem which affects not only those professionally involved but also the health of the people.

In accordance with the report of the joint committee which the American Chemical Society appears to regard as a Bill of Rights, "it should be illegal for any person not licensed by law so to do as to assume the responsibility of making the diagnosis or deciding on the progress or source of disease on the basis of any results of a chemical, pathological, serologic, bacteriologic, radiologic or microscopic observation, or other laboratory examinations undertaken, and that where laws do not now restrict diagnosis or the clinical interpretation of laboratory examinations to licensed classes of medical practitioners, laws should be enacted to effect that end. Hence any clinical laboratory which goes beyond the stage of supplying purely factual information on the results of laboratory procedures must necessarily be under the direction of a qualified physician in order to comply with the recommendations of this report. It may of course be left to the practicing physician whether he desires a simple laboratory report without any interpretation."

The interest of the patient is paramount. The apparent misinterpretation of the attitude of the medical profession by a sister professional society is unfortunate. Still more unfortunate is the use of the material that is being made by the enemies of all science.

## CRITICISM OF THE REPORT OF THE TECHNICAL COMMITTEE ON MEDICAL CARE

A very valuable analysis and criticism of the report of the Technical Committee on Medical Care on "The Need for a National Health Program" by Dr Herman H Riecker of the faculty of the University of Michigan Medical School appears in *Public Health Reviews* (8 25 [Jan 15] 1939), issued by the staff of the Division of Hygiene and Public Health of that university. The following includes the more significant portions of this review.

This evaluation of the report calls attention to but two points. (1) That to some readers it may reflect an unwarranted optimism toward the possibilities of national public health measures in the control of many phases of disabling disease, and (2) that its medical interpretations of statistical survey findings are often difficult to reconcile with current scientific conception.

The most striking lack of understanding of the problem of the prevention of illness by the committee is illustrated by the statement. The committee finds that the essential lack (in the national burden of illness) consists not of inadequate knowledge but of inadequate funds. It would seem however that cognizance of the lack of health education on the part of the people, the lack of orderly continuous educational opportunities for the physician, the extension of hospital and laboratory facilities and the need for further research in all fields of medical science would merit more serious consideration in planning for future betterment of health and medical service.

In considering the need for expansion of maternal and child health services the committee writes that the conservation of maternal and child life is especially imperative if we are to maintain in the future the proportion of persons in the productive ages necessary to an economically progressive nation.

adding that today there is a great and unnecessary waste of maternal and infant life, and that 'impairment of health is widespread among mothers and children.' It is quite possible that the increased life span has been the result of the application of increasingly effective control measures to certain communicable diseases of childhood, permitting more children to reach adult life. Particularly is this true of tuberculosis, typhoid fever, diarrheal diseases and diphtheria. It is not necessarily true that through public health procedures the life span will increase sufficiently to be a disadvantage to the nation economically or will cause a decline in the number of children, as the pamphlet implies. That impairment of physical health is 'widespread' among women and children would seem to deserve qualification because unweighted figures could scarcely give sufficient data to enable one to judge their significance from an 'economic' standpoint.

The pamphlet states that the maternal mortality for the United States was 57 per 10,000 live births in 1936, more than twice that of Sweden. It is true that there is an inadequacy of maternal and infant care in many sections of the country, but the fact that only 14 per cent of the births in rural areas occur in hospitals in itself could scarcely be accepted as importantly affecting the mortality rate. The use of newer procedures in obstetrics is attended by a very considerable hazard when employed by those not familiar with them. We would wish that the committee might analyze the difference in provision for maternal care in Sweden and the United States and proceed with recommendations from such an analysis. While prenatal care is essential and helpful in many instances an improvement in the actual technique and judgment at delivery will save more maternal lives than all other factors combined. The essential problem then with relation to maternal mortality is a recognition of the fact that most teaching institutions,

are inadequately supplied with clinical obstetrical material for both undergraduate and postgraduate teaching, that prenatal instruction to mothers is lacking, and that economic conditions enter significantly in the total reckoning.

With respect to the "special needs of childhood," the committee deplores the fact that "in 10 per cent of respiratory diseases pneumonia results, and that 18 per cent of the deaths resulting from diseases such as influenza, pneumonia, colds and tonsillitis are due to pneumonia among preschool children." The proper care of minor respiratory diseases is of the greatest importance in the prevention of complications and the problem of keeping sick children in bed at rest is a difficult task for any parent. In their prevention by a national health program doubtless there will be included provision for further research in the virus and streptococcal diseases, because we do not have a general preventive for influenza, colds and tonsillitis, and nothing but scientific research will provide one. May not the prevention of these infections and their complications depend more upon sound health education than upon the development of agencies which the public has not learned to use? In other words, should not greater stress be placed upon education?

The report further states "in the northern part of the country about 1 per cent of all school children suffer from rheumatic heart disease. Appropriate treatment of children with rheumatic disease will restore 60 per cent to normal life, 15 per cent to a life of restricted activity." Rheumatic fever has a predilection for certain families in a community and prevention of the attacks, probably by immunological procedures to be based on future research results is perhaps the goal of our hopes. However, from the medical standpoint, children with rheumatic heart disease have never been "restored to normal life" in more than 15 per cent of the cases, and these were usually cases with only a mild degree of aortic or mitral insufficiency. Clinical experience would seem to indicate that here again is somewhat undue optimism.

It would be interesting to know the sources of information for the statement that the maladjustments in the environment of the child will be corrected by tonsillectomy, the eradication of dental defects, or that these procedures save children from further illness and maladjustment, as stated on page 10 of the report.

In the advocacy of a national health program little is gained by the statement that upper respiratory infections are more common in a child of 9 than in an adult of 65 years. On page 11 the committee finds that the frequency of tonsillectomy and adenectomy among persons under the age of 20 years is only two-thirds as high in rural areas as in the large cities, and that filling and extraction of teeth are only one half that of children in cities of 100,000 population and over. The report possibly seems to favor the universal removal of tonsils and adenoids in children, a viewpoint for which further substantiation might be advisable, particularly in consideration of the belief now quite generally held that the hereditary allergic state plays a rather conspicuous part in upper respiratory infection.

With respect to cancer, the committee estimates that there are 400,000 persons suffering from cancer in the United States and that a large majority should be hospitalized when they cannot pay for the high cost of specialized and expensive service. The committee no doubt recognizes that education of the individual about cancer, and of the physician regarding the recognition and eradication of precancerous lesions, will probably continue to be the most important factor in cancer control.

Under the topic of diabetes, the committee states that the mortality from diabetes in young persons can be reduced by 90 per cent, and in persons over 60 by 37 per cent through the administration of insulin. It is, of course, well recognized by the medical profession that the control of obesity is fundamental to any decrease in the death rate from the degenerative diseases of the circulatory system and diabetes, and that the older "diabetics" do not die because there is sugar in the urine but from the arterial complications peculiar to their constitutional make-up. As a rule, diabetes is an incident, not a disease in the obese elderly person. It is suggested to the committee that if arterial degeneration is a public health

problem its amelioration might follow by public health methods applied to the overweight individual. Here again education rather than medical care would seem to be of primary importance.

With respect to the diseases of the heart, blood vessels and kidneys, without long clinical experience it is difficult to evaluate methods and possibilities of control of these conditions. There is no doubt that "much can be done through prevention and treatment to avoid needless cases of apoplexy, diseases of the kidney and circulatory diseases, to reduce suffering and premature disability and death and to minimize the economic and emotional distress caused by these diseases." The committee could scarcely be expected to recognize that emotional and hereditary factors often play a dominant part in the causes of the degenerative diseases (arteriosclerosis), and that coronary disease, apoplexy and hypertension are not commonly caused by poverty. A more hopeful prognosis is offered by wider application of the periodic physical examination by means of which vascular accidents in susceptible persons may be anticipated. Even so, the widely noted increase in the average life span should not be too eagerly interpreted to mean that immortality is within reach.

The committee believes that among the known means of reducing the disability due to chronic rheumatism are the care and removal of foci of infection, such as diseased tonsils and teeth, the treatment of gonorrheal infection, dietary supervision, specialized therapy, and surgery in some of the severe cases of arthritis. The committee believes that "90 per cent of these cases will recover or be definitely improved by careful and prolonged treatment." While the medical profession confidently hopes that research will find an effective treatment of rheumatoid arthritis, no such distinct optimism has been manifested in the literature, nor has it been shown that the removal of foci of infection such as diseased tonsils and teeth, has any curative and in many instances but little preventive effect upon the disease. In addition, any program of prevention of arthritis should take into consideration the important factor of individual susceptibility. Gonorrheal arthritis, however, is not a common condition in comparison to the incidence of gonorrhea, and is readily remedied at any stage.

That the Public Health Service should now expand in the field of mental disease is commendable for the reason that, while the care of mental disease has been a function of the state for several centuries of all the branches of medicine, research upon which prevention is based, has been most retarded in this field. It is hoped that a program in this field contemplates provision for accelerating the research problems incident to it. It would be interesting to determine whether behavior problems, dependency, delinquency and crime, as well as dementia praecox, the traumatic psychoses and abnormalities in behavior of childhood are largely preventable by public health measures. Biological factors involved in these conditions would need very careful appraisal by the committee before a general policy is adopted and in any plan substantial support of psychiatric research would be advisable.

There is general agreement with the committee that industrial hygiene programs should include the broad subject of the health of the worker. Experience indicates that a great many industrial workers are not interested in maintaining their health to the exclusion of certain other privileges they now enjoy, for instance, that of living in a city, the use of tobacco or alcohol, the cinema, the lack of sleep, and the use of available funds for gasoline rather than for vitamins. Health education and a solution of the problems of recreation on an individual basis would seem to be worth further discussion in promoting health consciousness among the low income group.

The report rightly emphasizes the relation of sickness to low income, and sickness with lack of employment. We must not fail, however, to associate sickness with ignorance concerning the cause of illness with inborn emotional maladaptations, disregard for the ordinary rules of health, and the accidents of ordinary life. We recognize that many sick people of the low income industrial groups do not have sufficient mental capacity or incentive to avoid illness. Even with munificent appropriations for public health, individual discretion nurtured by education might still be necessary in the avoidance of certain of the

common illnesses. The inexorable law of survival of the fittest is more difficult to suspend in people than in domestic animals for a number of reasons. In some instances even science must be content to provide an adaptation of the patient to his illness because prevention and cure are as yet impossible. If 60 per cent of the physician's practice is composed of neuroses which frequently are disabling, what public health measures should we employ to aid the physician in this field? There is no recognized method available at present by which social, economic, constitutional hereditary and environmental causes of human illness can be separately dealt with in its successful prevention.

In planning to extend the scope of curative medicine, the technical committee has no doubt given thoughtful consideration to the extension of preventive services, an analysis of the causes of illness susceptible to public health supervision, wide opportunity for the training of public health personnel, and a gradual

coordination and expansion of existing public health agencies as they fit into the picture. An improved quality of service by the doctor and a better appreciation of good medical service by the people are goals also worthy of attention.

Above all, technical minds should realize that while expansion and improvement of the public health and curative service in the nation are long overdue, the individual has some responsibility for his health and that of his family. There is a possibility that medical science is being pressed too hard for cures of hereditary, constitutional and neglected disease. A health program based on the philosophy of chattelizing the industrial lower income group in order to fulfill its ideal is open to question in view of the marked advance now being made by proven but inadequately applied alternate methods. We must not lose faith in the ability of ourselves individually to accomplish some measure of betterment in social and health matters if given the enlightened guidance of education.

## OFFICIAL NOTES

### ANNUAL CONGRESS ON INDUSTRIAL HEALTH

*First Annual Meeting held in Chicago Jan. 9 and 10 1939*

DR STANLEY J SEEGER, Milwaukee, in the Chair  
JANUARY 9—MORNING

#### Report of the Council on Industrial Health

DR STANLEY J SEEGER, Milwaukee. At the Atlantic City session of the House of Delegates in 1937 authorization was given the Board of Trustees of the American Medical Association to proceed with the organization of a Council on Industrial Health as a standing committee of the Board. This Council held its first meeting in December 1937. The plans of the Council include an investigation of present activities in the field of industrial health, the objective of this study being to outline problems of health in industry and to indicate what, at present, is being done about them. This conference represents one phase of this activity.

Industrial health as a field of special medical interest is relatively young. The implication of the development of industry and the change in the practice of medicine effected by workmen's compensation laws has not been sufficiently emphasized. That the leaders of organized medicine in this country realize the importance of these problems is evidenced by the fact that in 1915 the Section on Preventive Medicine and Public Health of the American Medical Association conducted a symposium on industrial sanitation, and in every succeeding meeting similar material has been presented. An exhaustive review of the possible effects of the then new workmen's compensation laws on the practice of medicine was presented to the House of Delegates of the American Medical Association in 1915 by the Judicial Council, who visualized the new social conditions which would be faced by medical men in connection with workmen's compensation in accident and in sickness. The tendency today to a wide extension of benefits under workmen's compensation acts illustrates the vision of those who analyzed the future effects of these laws at that early date.

The American Medical Association, because of its long standing interest in industrial health is cognizant of the excellent work which has been done in this field by various public health agencies and by private agencies as well.

According to the last Federal census there were about forty-nine million gainfully occupied persons of whom nearly fifteen million were found in the industrial establishments where a large percentage of our occupational diseases and accidents occur. The majority of these workers are employed in small plants. Of the more than eight million persons employed in manufacturing plants alone, about one half are found in factories with less than 250 workers. These men and their employers must of necessity look to the practicing profession for leadership in the field of industrial hygiene. This statement is made with a full realization of the important part which public health administrators have played in the past and must play in the future in the development of programs of industrial hygiene.

The terms "industrial health," "industrial medicine," and "industrial hygiene" are today greatly in need of clarification to the entire medical profession. The ambiguous and varied use and interpretation of these terms lead to a lack of understanding regarding the points under discussion and also of the purposes of programs which may be initiated by governmental agencies, by industry or by the organized medical profession. The connotations of the words "occupational" and "industrial" in relation to disease are further evidence of the necessity of a careful analysis of the terms used. The term "industrial medicine" has frequently been identified with industrial hygiene, industrial medical service, contract practice, insurance medicine and welfare work. The Council has recognized the necessity for clarifying the confusion and chaos which exist today in the minds of physicians concerning the limitations and objectives of industrial medicine. The introduction and improvement of industrial medical service open a vast complexity of problems. The relationship between industrial physician and management and the place of the physician in the factory await exact definition, as does the basis of relationship between the general practitioner and the industrial medical officer.

The practicing physician, whose interest in industrial health is obvious, must attempt to orient himself in this vast field, he must study the objectives and the accomplishments of the important agencies at work on industrial health problems, he must attempt to understand the point of view of those in government, in the labor movement and in industry who have sought to improve the health of the worker. The position of the full-time physician in industry must be defined and the ethical relationships which his work engenders must be reviewed, and definitions of terms used to designate various entities and practices must be formulated. The obvious dependence of the practicing physician on the industrial hygienist and the public health worker should be frankly stated and the efforts of these groups with a common objective should be correlated. In a similar spirit and in order to accomplish their professed objectives, public health workers both in industry and in governmental services must make a genuine effort to aid in the development of industrial health services through the agencies of organization of the private physician.

The deliberations of this conference should serve to outline the problems in this field and aid materially in their solution.

### SYMPOSIUM ON INDUSTRIAL RELATIONSHIPS

#### The Physician in Industry and Organized Medicine

DR IRVIN ABELL, Louisville, Ky. Organized medicine has throughout its existence considered that the preventive and curative health needs of all the people are best controlled by two agencies—public health administration and the private practice of medicine. In the opinion of the majority of physicians there has been as yet no incontrovertible evidence that industrial medicine should not conform to this basic pattern. Public health administration has devoted a growing segment of its resources and interest to the control of industrial hazards for more than

a quarter of a century. The broadening nature of its present proposals, particularly the recent rapid extension of industrial hygiene bureaus into the state departments of health and the difficulties which have been encountered, are therefore viewed with uncommon interest. It is important to all practitioners that they become well acquainted with these bureaus not only as sources of information and assistance but because full usefulness can never be attained by these agencies unless confidence and support are enlisted from all elements in the profession.

Medical relationships in industry, as far as the individual physician is concerned, differ from ordinary practice in that the preventive aspects by reason of their clinical and technical complexity are more sharply set apart. In comparison, it can almost be said that industry has produced few new problems on the curative side. Nevertheless, so long as plants and workmen in good majority depend on part-time medical personnel, many physicians will be obliged to administer industrial hygiene on the one hand and continue their customary management of individual patients derived from industry on the other. These dual responsibilities are of first importance and not always realized even in professional circles. For some time to come, any movement to improve or extend industrial health must acknowledge first of all that in speaking of industrial hygiene and physical rehabilitation we are describing the several functions of the same set of practitioners. Indeed on occasion these functions may overlap yet there is no incompatibility that suitable training and ethical behavior cannot overcome.

*The Objectives of Industrial Medicine*—It became apparent early that certain basic precepts must govern the attitude of organized medicine toward the modern industrial health movement. One of the earliest convictions to assume shape in our collective professional thinking was that the true domain of industrial medicine could be defined and that organized medicine had an obligation to see that such boundaries and limitations as were erected are well known and observed. To quote from an editorial in THE JOURNAL of some years ago, the objectives of industrial medicine should be: 1 To fit every person to types and quantities of work according to his ability to perform such work continually without undue impairment without injury to himself or his fellow workmen and with profit to himself and his employer. 2 To procure and maintain fitness for work through efforts applied to the worker as an individual, to groups of workers and to the work environment. 3 To educate the worker to a comprehension of the value and significance of physical and mental well being and in particular of personal hygiene and accident prevention. 4 To reduce all loss of time, absenteeism and short work spans in industry the cause of which may be related in any way to health. These frequently quoted principles are widely acceptable as a general statement of policy not only to private practitioners but to most industrial physicians as well. Few have expressed disagreement with the contention that the functions of industrial medicine should be—beyond specific legal requirements—confined to preventive practice within the working place. Furthermore, all concede that no real progress will ever be made until the worker himself is led to assume an intelligent personal interest in his own physical welfare and the conditions of his working environment. Any aloofness which individual physicians may have demonstrated toward industrial practice and which has communicated itself to organized medical groups has arisen from the variety of conditions under which industrial health control has escaped from this definite framework. If one accepts these stated qualifications as marking the attributes of acceptable industrial medicine, it becomes clear that many activities which by long association have come to be considered as functions of industrial health programs are not so at all. The needs of certain industrial localities may have given rise to extended medical care community wide in scope and with the family as a unit. Such an arrangement may or may not have been necessary or adequate—in any case, it is not industrial medicine. Similarly, the physician in an industrial community may supply a degree of management to individual cases arising out of industry which leaves nothing to be desired, yet by *our definition* he meets only partially the demands of a satisfactory industrial health program. To the extent that the physician in industry has been guided by these principles, to that same degree has he commanded a position of worth and respect in the eyes of the profession at large.

*Elevation of Standards*—Organized medicine has an obligation to stimulate a widespread genuine interest in elevating standards of industrial practice. No other agency has in any approximate sense the opportunity to bring to the individual physician a real awareness of his place in the industrial setting. The whole background of enforcement of standards in other fields of medical interest provides easy transition to and concentration on the clinical content in occupational diseases and injury. The entire fabric of the ethical code takes on unusual significance in its adaptations to the health control of the working population. The condemnation of quackery and cultism is as important in industry as elsewhere. The provision of sound medical literature and the regular evaluation of clinical experience and investigation are needed in industrial medicine quite as much as if not more than in other fields. Industrial health has benefited from every advance made by organized medicine in the direction of its own self improvement by controlled undergraduate instruction by adequate standards of licensure, by supervised internships, residencies and fellowships, and by the appraisal of results based on clinical records, laboratory investigation, autopsy performance and hospital staff conferences. The industrial physician can expect to profit to the same extent as others by the upsurge of interest in postgraduate medical education and the development of standards for specialty practice out of which the public is constantly receiving improved medical service both in industry and out of it. It is recognized, of course, that the profession has not been uniformly well trained to a full comprehension of its preventive functions in industry. If medical men are to maintain leadership in industrial health, much more attention will have to be directed toward a reasonable degree of preparation in the fundamentals of industrial hygiene. To overcome this lack of information is, as I visualize it, one of the primary objectives of the Council on Industrial Health. There is in organized medicine the immense advantage of structure. The community of interest which exists between national, state, county and local medical groups exerts a profound influence on the individual membership in his medical society meetings committee activities and personal associations. The formation of committees on industrial health which are being developed in the state medical societies and by predictable extension into the counties provides a machinery for cooperative enterprise the ultimate accomplishments of which are incalculable. As this arrangement perfects itself, working relationships will be established between all agencies having a legitimate interest in industrial health. Few physicians then will be able to complain of poor or absent sources of information for the solution of industrial problems and very few outside the profession that proper medical interest is not ably and intelligently represented. Organized medicine reaffirms its conviction that no industrial health system can ever be considered worthy of that name unless the worker himself is constantly upheld as the central object of all effort, all planning and all reform. As long as this attitude prevails and reflects a single minded purpose, then can labor, management the government and all elements within the medical profession meet on common and substantial ground.

#### The Physician in Industry and the Employer

DR C. D. SELBY, Detroit. The physician was first employed by industry to treat occupational injuries. Although the employer was the responsible party and the physician acted as his agent, the relationship was principally that of doctor to patient and as such it did not differ from the relationships which characterize private practice. The doctor was not an integral part of the employer's organization. Out of this original arrangement has been evolved a working plan which integrates the doctor with industry and also utilizes his abilities in the field of preventive medicine something new in principle and practice to both medicine and industry.

For complete understanding, it is necessary that the employer's medical needs be considered.

*1 Medical and Surgical Care*—The ordinary surgical and medical functions of the doctor in industry may be dismissed as not differing from those of private practice. The physician furnishes the services either directly or through consultants. From this point on, industrial medicine diverges from private practice and assumes an individuality peculiar to industry which determines the relations of doctor to employer.

**2 Control of Exposures**—Employers do not wish to see workmen harmed through occupational conditions, and they are willing to furnish reasonable protection by way of mechanical safeguards, exhaust systems, changes in processes, and so on. The physician is in a position to observe the results of failure of protective measures and is called on to treat the resulting conditions occurring among the exposed workmen.

**3 Physical Supervision**—This is the term commonly applied to physical examinations of workmen. No one but a plant physician can adequately render this service.

**4 Records**—For the fair evaluation of compensation claims and the maintenance of the health of employees, fairly complete records of each workman's contacts with the doctor are essential. The employer expects him to keep such records. The employer looks to the doctor for guidance in making his plant safe and healthy and depends on him for safe placement of new workmen, the continued safe employment of all workmen, prompt and effective treatment of occupational injuries and diseases and unbiased opinions as to the validity of claims for compensation.

For managerial purposes the health service is usually placed in the personnel department. An able personnel manager can be very helpful to the doctor. He pleads with the employer for him, he supports his decisions and he correlates the medical with the other personnel functions. In a small plant the doctor should report directly to the employer. To merge the medical with the employment function is likely to circumscribe the medical and make the employment features of the service dominant. Likewise to merge it with a compensation department has a similar effect except that it then becomes chiefly an accessory in the settlement of claims.

For the broad application of medical knowledge to the benefit of employee health, it is necessary for the doctor to be high enough in the management structure to avoid the influence of special but limited interests. For determination of the medical functions that have a useful application in industry the employer is dependent on the doctor, but his acceptance of the doctor's recommendations is influenced by his confidence in him. To gain the employer's confidence he must demonstrate his worthiness as a physician and evidence sufficient knowledge and interest in the employer's primary objective to justify confidence. The employer's primary objective is the maintenance of a productive working force at a cost that permits profitable manufacturing, and he knows that industrial medicine is capable of making a considerable contribution toward that end.

### The Industrial Physician and the Employee

DR LOYAL A. SHOUPE, Bethlehem, Pa. There is a difference between the physician who spends his full time in an industry and the one who spends an hour or two a day or week and the rest of the hours in private practice. There is a difference between the physician who spends his full time in the industry and the physician who sets up a so-called industrial clinic giving his time mostly to the minor surgical needs of the various industries in that district. In some industries the force will be entirely male in others predominantly female, and in others there may be an equality of the sexes, but the broad principle of relationship between the industrial physician and the employee remains the same. We who have been in this work for twenty or more years have seen a shifting of emphasis from the curative stages of medical care to preventive work and health education. We have seen the trend from the surgical phase, then the medical phase, the job placement phase, the supervision, the cooperation with the engineering group, the control of exposures, and all to the end that better working conditions shall prevail.

I should like to discuss my idea of the type of physician who should be in industry. The practice of medicine is an art and if there is any phase of medicine which requires an artist it is the industrial phase. Unless a man has a real calling for the work, real love for his fellow man, he should not enter this field. A man presenting himself for examination for a job has a right to expect that he will be given every consideration, that he will be allowed to work and that if found unfit for one job he will be recommended for other work for which he is physically and mentally fit. He has a right to expect a thorough examination to know the results and to believe and to know that this communication is privileged.

Physical examinations of the men and women who apply for jobs should be conducted in a pleasant, courteous and friendly manner. The doctor at this time has an opportunity to impress on the man the necessity for keeping himself in good health and to point out any dangers that may be connected with the job. He should tell that man, if he deems it necessary, to report for reexamination or check-up. It is his duty to see that no man is placed in a job where he will be a danger to himself or to others. Medical service must be confined to accidents while on duty and occupational sicknesses or any emergency treatment of the illness occurring on duty. The employee may receive a periodic examination at any time, and any condition found in such an examination should be reported to the physician of his choice, so that he may receive proper treatment. An employee should be assured that the results of examination are confidential and returned in that manner by the industrial physician and he should receive the same consideration and attention as he would receive in the private office of his own physician. There should be no preference given to any class of employee, office or shop, labor or supervisor. The extent to which this is carried out will become a large factor in an employee-physician relationship, and the attitude of an employer relative to the physical well-being of his employees is directly reflected by the physician in his daily contact with the employees. As a member of a personnel organization, the physician must train himself to feel that he is definitely a part of the industrial machine—a member of the same dinner-pail carrying gang that makes the wheels go round. He alone of all the management machinery is best entitled with the exception of the immediate superior, to call employees by their first names, and this aura of familiarity can be penetrated with no loss of dignity provided it is rightly done. Sometimes the employee expects too much, in that he expects the physician to care for ills which are not directly connected with the industry or to treat him for an accident which had no connection with his job. At times this presents a difficult situation, but the medical department of any industry should establish the fact that it is there only for the conditions arising in and out of the industry and if a man becomes ill on the job from another cause and it is necessary for him to leave the job, he should by all means be referred to his family physician and the physician in industry should cooperate with the family physician.

The problems are many, varied and interesting. There is no place where one comes in such close contact with the working man as in the plant clinic and it is here that the greatest lessons in health can be put over. The all-day clinic is a great melting pot for human experience. Sometimes a man is unhappy. Relations with the men about him or with his foreman are a constant source of irritation. The right mental conditions are as important to the welfare and efficiency of workers and have as much to do with output and profits as do physical conditions. I know there are men who can always find some new ache or pain and are willing to swear that the job they are doing is the cause. The doctor must carefully examine the man and guard against permitting such men to blind him to the real ills of the honest man and the employee has the right to appeal to the industrial physician through his sickness to continue on the job and to appeal to him for a change if found necessary. I believe that to no other man is given as great an opportunity to promote a better mutual understanding and relationship between the employer and employee as is given the doctor. He should understand the workings of the plant and must at all times work in harmony and cooperation with the various departments. Mental ailments need treatment. Harsh words, sarcasm from a superintendent gives to the doctor his hardest job. Fears of all kinds, discontent, lack of a living wage, worry of sickness, trouble at home, a love affair, bad habits and innumerable other things undermine the health of employees and it is as essential to remove these conditions as it is to tie up a cut finger. Perhaps you will say that these are not industrial problems, nevertheless they are problems in the day's work. I feel that the personal relations between the doctor and the employee are of great value. An employee wants to feel that the physician in the industry is what we call a good doctor, that the physi-

cian has his well-being at heart, that the physician understands him and his job, that the physician is fair in all his dealings with all the men, that the medical clinic is the place where he can turn when in trouble. While not all of this is a function of medicine, listening to other people's troubles has become an obligation to physicians, whether in the home or in the factory. It is a tribute that the whole world pays to the physician. The plant doctor should betray no confidences. He must at all times be fair. His position as adviser to the employer and big brother to the employee, although delicate, has opportunities which he must recognize in order to succeed as a plant doctor. Things may break badly for the lowest man in the plant the same as for any one else. There are times when a cheerful word means more to a man than you can tell. If a corporation has no soul, it is the physician's duty to put a soul into it.

#### Industrial Health and the Private Practitioner

DR ROSCOE L. SENSLEIGH, South Bend, Ind. It has been reported that 98 per cent of American industries employ less than 500 men each. In the ninth largest industrial state there are 3,964 industrial plants, of which 85 per cent employ less than 100 workers each. All these groups have problems of industrial health. The manner in which their medical and surgical needs are served varies accordingly. The larger organizations employ physicians and surgeons on a full-time basis for a fixed compensation. The actual number of physicians occupying such positions is not available, but the American Medical Directory records only 345 who reported that they were limiting their work to this field. Industrial medicine and surgery was reported by 1,054 physicians as their special interest. For additional income these physicians are permitted to carry on such private practice as time not required in the company service will permit. However, the company service is the major commitment to this group of physicians. Lesser industries are served in the main by modifications of private practice. Individual surgeons or professional partnerships of surgeons frequently maintain headquarters manned at all times for emergency service. These serve a number of establishments on varied types of contractual or fee schedule bases. Practitioners whose major practice is private are called or consulted by prearrangement as needs develop in certain establishments. Other private practitioners may be less closely related in that they are designated by insurance companies as ones who may be called in emergencies and have no part in safety or preventive medicine. Such services as are required are generally paid in accordance with a fee schedule previously fixed by the employer or insurance company.

From the foregoing study it is apparent that the contact of physicians with industrial health varies from one of major interest and livelihood to that of minor interest and more or less accidental employment because of immediate availability in an emergency, for which they are paid on a fee basis. The fee basis is generally fixed at a level below the standard for private practice. This classification is obviously according to the financial plan of employment. In professional qualifications this may represent the difference between a carefully selected and thoroughly capable man and one less capable, whose selection has been determined at least in part by his willingness to serve according to the terms of a fee schedule on a basis not generally acceptable.

The medical service provided varies from the highest type, embracing research in the physiology of work and the influence of varying conditions under which the work is carried on, preventive medicine, instruction in hygiene, and safety measures. Diagnosis and care of disease conditions and injuries arising from employment are carried on under the direction of capable medical men. The other extreme may include only the minimum of medical and surgical service required by law and given by men of less training, having no special interest in industrial health, employed only when called. Even with these variations it is evident that there is nothing incompatible between the medical and surgical service of industrial health and private practice. The private practitioner has more often treated the major-interest industrial surgeon with what has been described as a noticeable "aloofness." Less frequently he

has been openly critical of the industrial surgeon's attitude toward company employees or of his personal business practices. The industrial surgeon in turn has generally assumed a position of belligerent defense toward his critics, or frequently, if on part-time private practice, he has aggressively used all the advantages of his industrial connection in a drive for personal medical gain.

It is to be regretted that, with some employers, willingness of some medical men to accept contracts for a low salary has been too highly rated as a qualification for employment as industrial health surgeons, and character of service has suffered. A better appreciation of the value of good medical supervision and service to industry should rapidly correct this condition. Society requires that the employee shall be protected against unnecessary hazard and that he shall be given medical care and compensation in the event that he suffers illness or injury by reason of that employment. The law requires that the employer give evidence of his financial ability to carry out legal requirements as to medical care and compensation or that he carry insurance with a responsible insurance company. The financial motive directs that it is advantageous to the employer to require at least some measure of examination to determine the physical and mental condition of the prospective employee before assuming contractual relations of responsibility for what may happen in the event of his employment.

The employer may entertain an interest in the well being of his employees. However, the insurance company is a step further removed from the employee than the employer and is concerned in preventive measures only so far as they diminish the chances of losses which may be sustained because of compensable conditions resulting from employment. It is not a producer of things but is dependent for its profits on the satisfactory adjustment of claims for injuries or disease resulting from employment. Finally, and of paramount importance, are the health interests and financial interests of the employee for whose protection all these provisions have been set up. It is presumably in his interests that the industrial physician is employed. The extent to which his interests are given consideration and the fairness of established policies are questioned at times by representatives of employees. It is at this point that the industrial physician and the private practitioner most often meet.

The industrial physician serves both the employer and the employee in all his efforts in disease and accident prevention. The physician is obviously interested in protecting his employer against malingers and against unwarranted claims by employees. Concerning the latter, there may be grounds for difference of opinion. The treatment given an employee may not be satisfactory to the employee or his family. This position of the industrial physician is difficult in that in some states the employee must accept the services of the physician named by the employer or, if he seeks other medical care, the employer is not liable for the fees. Finally, in compensable conditions the industrial physician may be placed in a position in which he is supposed to represent two parties whose interests may be directly opposed. Therefore, if the employer and the industrial physician do not offer the consultation service of a neutral consultant, the employee is forced to employ a physician in private practice to present medical evidence before legal adjudicating boards. Many times the private practitioner presents opinions at variance with those presented by the industrial physician.

It has been charged that the private practitioner too frequently appears as the advocate of the employee in exaggerated claims. The private physician may have little or no experience in the condition under question and therefore he has been described as having a tendency to testify according to such theories as he may develop rather than according to knowledge generally accepted by those of greater experience. On the other hand, there is complaint of failure of industrial physicians to utilize the services of specialists in private practice in the diagnosis or treatment of conditions for which they have not had training or experience comparable to specialists in their community. Present methods of fixing responsibility and determining degree of disability as a result of conditions

of industrial employment tend to emphasize any difference of opinion and accentuate this suggested divergence of interest between the industrial physician and the private practitioner. Private practitioners point out that the part-time contract industrial physician who spends the remaining time in private practice is placed in an advantageous position with the employees of his company to obtain private practice. Private practitioners point out that the industrial physician is attached to both the welfare and personnel departments generally and passes on physical fitness for employment. The implication follows that it is advantageous to court the friendship of the industrial doctor. Complaint has been made of the utilization of plant x-ray or other laboratories, installed primarily for employment examinations and care of minor conditions resulting from employment, in the diagnosis or care of conditions not related to employment. It is said that in some instances these facilities are used by industrial physicians in private practice in competition with private practitioners. Systems of group insurance medical service are said to have been established and are carried on by the industrial physician in competition with private practice. Obviously, there is no mystical formula which can be applied to adjust so many and varied points of contact. However, a general view of the matter suggests that the principal causes of tension might be eliminated by action directed along the following lines:

1. Improvement of the medical standards of industrial health activities. Provision should be made for better education in industrial health. There would seem to be ample ground for a certain degree of specialization if study and control of conditions of labor, light, ventilation, noise, posture, character of effort required, fatigue, exposure to deleterious substances and relation of trauma to disease are given adequate study. Recognition of specialization in this field to such an extent as may be logical and helpful may be suggested. On the other hand, there should be greater utilization of the established specialties in other fields of medicine, in consultation and care of certain diseases developing in industry. Specialization might seem to be inconsistent with compensation laws in various states which now permit employees to select their own surgeons for treatment of industrial injuries. However, experience in specialization in other lines suggests that recognition by the public that special training in a field tends to attain better results prompts the selection of better trained men in each specialty by those who choose to select their own surgeon. Further study should be made of the experience in those states in which free selection of surgeons in industrial cases is now permitted. Perhaps some modification of these plans would be helpful. Industrial physicians should not assume at company expense treatment of conditions not properly belonging to industrial health.

2. Cooperation in the creation of such intraprofessional machinery as will provide examination by neutral consultative groups of employees presenting claims for adjudication. When legally admissible, the reports of their conclusions should be submitted to industrial boards or courts. This would tend to avoid the presentation of conflicting material concerning claim cases before legal boards composed of laymen who are forced to make conclusions and awards from this basis. It would tend to discourage the overemphasis of minor observations and presentation of unfounded claims for conditions alleged to be the result of employment. The relationship between industry and the private practitioner is becoming more complicated because of recent dissatisfaction on the part of labor. Requirements for employment, discharge for physical incapacity and the like have been opposed. In some instances labor unions have hospitalized employees having claims, under physicians employed by the unions. Evidence thus obtained has then been presented by the physicians and lawyers employed by the unions. Acceptance of employees having minor impairments to employment for selected duties would necessitate a much closer contact and cooperation between industrial physicians and private practitioners. The Wayne County Medical Society, Detroit, has just completed the organization of means to adjust differences between attending physicians and insurance companies in matters of question between them. This is a very valuable step in the right direction.

3. Cooperation of industrial physicians and private practitioners in exploration and determination of boundaries of industrial health and private practice. The employer, the employee, the industrial physician and surgeon, and the private practitioner need more knowledge about the problems of individual health in industry. Industrial medicine may contribute much to medical knowledge in preventive medicine through research, by reason of the opportunity to observe the effects of labor on large groups under conditions approximating those of controlled experimentation. New techniques in treatment of industrial diseases may be developed because of the opportunity to observe large groups. On the other hand, because of the limitations to which specialization may be developed within the field of industrial medicine and the restricted scope of treatment properly belonging to industrial medicine, it must always be dependent on the clinical research and broader clinical experience of private medical practice for basic medical information. Medical and surgical conditions require the same treatment regardless of the cause, in industry or out of industry, and it is evident that such differences as have been apparent between industrial medicine and private practice are the result of the financial and legal factors which influence employment and industrial practice. However, private practice has always operated as a check against harmful tendencies and a balance against destructive economic practice. So long as private practice is free from control it will continue to do this. Industrial medicine will be respected in proportion as it will apply itself to the advancement of accident prevention and the maintenance of the health of the worker within the boundaries of industry, provided the material interests of industry are not permitted to introduce between the industrial surgeon and his employee patient elements prejudicial to the best interests of the employee and inconsistent with the ideals set up for private practice.

#### DISCUSSION ON INDUSTRIAL RELATIONSHIPS

DR. A. S. LEVEN, Chicago. It is fitting that the first Annual Congress on Industrial Health by the American Medical Association has been opened with a symposium on the relationship of organized medicine toward the physician in industry and the relationship of the industrial surgeon to the private practitioner. The introduction of medical service into industry has been a laborious task. Although industry deals with machinery, materials and labor, it does not regard all three in the same category. Many industrialists have as yet failed to realize the full importance of the fact that a healthy worker steadily employed or a sick worker quickly restored to health means more profits for industry. Many industrialists have failed to realize that the maintenance of the worker's health is of more importance than the maintenance of machines. Many industrialists still regard the worker as of secondary importance. Industry itself has been an obstacle in the introduction of medical service into industry. Only in recent years, owing to pressure of labor groups, social agencies, governmental and legislative bodies, and persistent educational procedures on the part of organized industrial medicine, has the health of the worker and his working environment been considerably improved. The medical profession especially organized medicine, has also been an obstacle to the introduction of medical service into industry. Had the medical profession as a whole taken a more active part in educating industry to the tangible value of medical service, to the health of the workers and to healthful working conditions, this attitude might have been changed long ago. But the medical profession until recently looked down on industrial medicine. Because of these facts, industrial medicine and surgery has had in previous years a slumberous career. Only recently has the American Public Health Association seen fit to establish a Committee on Standards of Practices in the problems of compensation and of industrial diseases. Only recently has the American College of Surgeons seen fit to put forth a program of the American College of Surgeons in industry. Where has organized medicine been with reference to the problems of the physician in industry? During these times industrial physicians have organized and today industrial medicine and sur-

gery has become a unified body and finds expression in such national organizations as the American Association of Industrial Physicians and Surgeons, the Association for the Advancement of Industrial Medicine and Surgery, and various local and state industrial medical specialty societies. Slowly, but surely, industrial medicine has become a penetrating influence in the world of industry and in the medical profession as a whole. Industry is beginning to give the industrial surgeon the respect and the acknowledgment which he deserves. Organized industrial medicine and surgery has disseminated accurate medical knowledge with reference to the diagnosis and latest methods of treatment and evaluation of all conditions arising in the course of employment. Today our social, political and economic standards are rapidly changing to new forms, and as physicians and as citizens we are greatly affected by these changes. Organized industrial medicine will help the entire medical profession to progress. In addition to his actual professional knowledge, the industrial surgeon must have contact with and knowledge of medicolegal, medico-engineering and socio-economic problems, which are rarely encountered in the routine of the private practice of medicine. Testimony on questions of permanent injuries and evaluation of disabilities involve the industrial surgeon in a proposition that is not the usual sphere of the average practitioner. There is only one common ground on which medical analysis of a physical handicap can stand, and that is the status of function. Only the physician trained or experienced in industrial medicine and surgery, or the orthopedist or traumatic surgeon, is capable of determining fitness through analysis of function. By giving industrial medicine the recognition it deserves, organized industrial medicine will be stimulated toward greater efforts and efficiency and will be able to attract other competent physicians and surgeons to this special branch of medicine.

Dr. AUSTIN HAYDEN, Chicago. According to the last speaker, organized medicine is behind the times. Here in Chicago I have known industrial surgeons for a long time and they have been conspicuous by their absence in the councils of the Chicago Medical Society and the American Medical Association. In the Board of Trustees where this Council originated at the time it was being originated I took occasion to look back through the files of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* for five years and I came to the conclusion that at least a third of the articles were quite obviously connected with industrial medicine in one phase or another. The American Medical Association is delighted to have this gathering here this morning. We look forward to the development of every phase of industrial medicine as it has to do with private practitioners and practitioners who limit their activities to industrial medicine and, far from being asleep, I think the march of medicine in industry in the United States has been as great as the march of medicine itself has been in this country compared to the march of medicine elsewhere in the world. After all, doctors have to do with human beings. The American Medical Association has been called "the family physician of the American people," and the industrial surgeon is an important part of that. Within the last two months I have been engaged in the determination of the deterioration of hearing in industry where workers were subject to a large amount of noise. The object of that was for the company's protection as well as for the worker's protection. It is simply an extension of the general physical examination which most companies require of their employees, and we found to our amazement that men who had been subject to 105 decibels of steady noise—which is a very heavy noise, up to, under some circumstances, 125 decibels, which is about equal to the explosion of a small cannon, within a period of months—showed, without exception, a reduction in the upper scale of the hearing range. It seems to me that men with imperfect ears, if they desire to be placed in that particular department of this corporation, should know when they go in that there is a risk. The company is anxious that they know they are encountering this risk. They should know what amount of hearing they go in with and what amount of hearing they come out with, and that should be a responsibility mutually between the employer and the employee. It is the

beginning, in industrial medicine, of the conservation of human beings and the safeguarding of the interests of the employer.

Dr. JOHN N. HOLCOMB, Grand Rapids, Mich. In the chairman's introductory remarks it was of interest to me to hear of those on full time, those under part time, those under contractual arrangements and those who were free lance. There was also brought out the question as to the number of organizations. If that percentage follows through, it is evident that a substantial amount of this work is being done by men perhaps like myself, who are free lance, so to speak. The question came with regard to the financial returns. It has been my particular observation that good companies are looking for service rather than price. The question of examination enters into the picture. So far as preemployment examination and continued employment examination are concerned, that must be classed definitely as an instructive type of examination. The type of examination directed toward the elimination of the employee should be decidedly discouraged and unknown in the field. The surgeons in general are very much in harmony with that thought. We must not adopt standards so high as to bar from employment the average man who wants to work. A highly important thing is that legislation should be so made, so built up, that it gives men an opportunity to work without undue discrimination or undue expense to the particular employer. For those of us who are located in smaller towns which have no industry large enough to support a man independently, it is necessary from an economic standpoint that a man be not limited to carry on with one single company. With that in mind we must recognize that there are none of us who probably are capable of handling all the particular situations that come up. It seems evident that a man doing good, constructive work of this type is certainly going to call on those men who specialize in that particular field.

Mr. MARSHALL DAWSON, Washington, D. C. The United States Bureau of Labor Statistics has recently completed a survey of workmen's compensation administration which is, geographically, probably the widest thing that has ever been done, because it has covered the United States, Canada and Puerto Rico. If industrial physicians, becoming acquainted with such situations as have been pointed out by Dr. Hayden, would route that information into some central clearinghouse interested in labor, either the United States agency for promoting vocational rehabilitation or the United States Bureau of Labor Statistics, a great deal of good might be done. The agency charged with the task of vocational rehabilitation may be anxious to place certain deaf persons, for instance, in just those processes. You can readily see that the remarks of Dr. Hayden have opened up possibilities not only for giving employment to certain men who find it difficult to find employment but the opportunity for saving the hearing of men with normal hearing. I simply pass on the suggestion that any of you who have become acquainted with such special situations as those commented on by Dr. Hayden report the matter, with the name of the industry in which the occurrence is taking place, either to the Bureau of Labor Statistics or to the United States Office of Education, the Department of Vocational Rehabilitation.

Dr. SEEGER. I think it will be of interest, in connection with Mr. Dawson's remarks relative to clearinghouse possibilities, that one of the early arguments favoring the formation of the Council on Industrial Health was advanced by the Section on Dermatology and Syphilology of the American Medical Association with this very point in view. Dermatologists, as you know, both in private practice and in the United States Public Health Service under Dr. Schwartz, have done a tremendous amount of work in the field of industrial dermatology, and it is desirable because of the presence of dermatologic conditions in industry to disseminate information to men who practice without the opportunities of clinical material. The possibility of a clearinghouse for various fields is being reviewed by the Council, but it is, as Mr. Dawson and all of us must realize, a tremendous task and offers some very practical difficulties which I hope, as time goes on, it will be possible to solve with your help.

DR LOYAL A SHOUDY, Bethlehem, Pa I still want to say that what industry wants and what the employee wants is the good doctor in industry We want it from the standpoint of the employer and we want it from the standpoint of the employee Dr Marble is going to go ahead on that

DR H C MARBLE, Boston I agree with Dr Shoudy that what is needed in industrial work is better doctors, as better doctors become interested in the treatment of the industrial sick and injured the problem will take care of itself Our problem in the future is the problem of education, the getting of adequate teaching in the medical schools, the getting of better teaching in the graduate schools Until we get more training more graduate teaching in our medical societies, our discussions about the inadequacy of certain physicians avail nothing We have got to have better doctors doing industrial work

MR E T BUCKINGHAM Bridgeport, Conn Might I ask a question? The doctor from South Bend Ind, brought up a question that is very interesting to us commissioners where we have a hearing and one doctor says "Yes" and another doctor says "No" and then you select a third How do you arrange for the payment of the third physician? We are troubled with that problem all the time

MR DAWSON In most states that amount is charged directly to the insurance carrier Most compensation administrations do use that impartial physician

DR HAYDEN Maybe the reason you had to bring in a third party was that the original physician or employer or employee did not have the proper standards by which to evaluate their observations Dr William P Wherry is interested for the Council on Physical Therapy is evaluating hearing loss in the same way that the original evaluation was done in 1916, beginning in the Section on Ophthalmology of the American Medical Association, for vision When that is done when we can come before a court and say that a man is disabled to a certain extent and to exactly what extent he is disabled by a

certain hearing loss, maybe the necessity for third party consultants will be much less I should like to hear from Dr Wherry

DR W P WHERRY, Omaha The program has not as yet gotten far enough under way to discuss it I would prefer to hold that for a later date

(To be continued)

## RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company entitled "Your Health," began Wednesday October 19 and will run consecutively for thirty-six weeks The program is broadcast each Wednesday over the blue network of the National Broadcasting Company at 2 p m eastern standard time (1 p m central standard time, 12 noon mountain time 11 a m Pacific time)<sup>1</sup>

These programs are broadcast on what is known in radio as a sustaining basis that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs Therefore local stations may or may not take the program, at their discretion except those stations which are owned and operated by the National Broadcasting Company

The next three programs to be broadcast together with their dates and their topics, are as follows

February 8	Avoiding Arthritis
February 15	Healthy Hearts
February 22	Cancer Can Be Cured

1 Owing to program conflicts there will be no Chicago broadcast of the network program Instead a recording of the program will be broadcast over station WENR at 8 p m each Wednesday This recording will be an identical rebroadcast of the network program broadcast earlier the same day

## MEDICAL LEGISLATION

### MEDICAL BILLS IN CONGRESS

*Bills Introduced*—S 569, introduced by Senator Hatch New Mexico, proposes to extend the provisions of the United States Employees' Compensation Act to enrollees in the Civilian Conservation Corps suffering disability or death resulting from injury while in the performance of duty S 672 introduced by Senator McKellar Tennessee, and H R 1520 introduced by Representative Taylor Tennessee propose to indemnify certain named physicians in the amount of \$10 000 each for loss of practice due to the flooding of areas in which they formerly engaged in practice, resulting from the construction of the Norris dam S 1007, introduced by Senator Bone Washington provides that the licensed personnel of the Bureau of Marine Inspection and Navigation Department of Commerce regularly engaged in the inspection of steam and motor vehicles and the licensed local pilots actively engaged in piloting vessels in the United States waters shall be entitled to medical relief without charge at the hospitals and other stations of the United States Public Health Service, under the rules and regulations governing the care of seamen of the merchant marine S 1021, introduced by Senator Sheppard Texas proposes to extend the benefits of the United States Employees' Compensation Act to members of the Officers' Reserve Corps and of the Enlisted Reserve Corps of the Army who are physically injured in line of duty while performing active duty or engaged in authorized training H R 1950, introduced by Representative Bland Virginia proposes that commissioned officers of the United States Coast and Geodetic Survey and their widows children and dependent parents shall be entitled to the benefits administered by the Veterans Administration under the same regulations and restrictions as are or may be provided by law with respect to officers of the Army Navy Marine Corps and Coast Guard H R 1985 introduced by Representative Robison Kentucky proposes to reenact all

laws in force on March 19 1933 granting presumptive service connection of disease or disabilities to World War veterans H R 2296, introduced by Representative Rankin Mississippi proposes that, after the date of enactment of the bill any World War veteran suffering from paralysis, paresis or blindness or who is helpless or bedridden as the result of any disability may be awarded compensation under the laws and interpretations governing this class of cases prior to the enactment of the Economy Act of March 20 1933 H R 2893 introduced by Representative Izac California proposes that hereafter retired enlisted men of the Army, Navy Marine Corps and Coast Guard when hospitalized or domiciled in either an Army or Navy hospital or United States naval or United States soldiers home, shall be extended such treatment or domiciliary care without cost H R 3055 introduced by Representative Randolph, West Virginia proposes to provide for the retirement of nurses attendants or orderlies in any neuropsychiatric hospital or ward in any hospital operated by the government of the United States after the completion of twenty-five years of service H R 3115 introduced (by request) by Representative Buckler Minnesota proposes to extend the status of veterans of the World War to persons enlisted and serving on United States Shipping Board vessels during the World War in war zones H R 3137 introduced by Representative Spence Kentucky, proposes to authorize an appropriation of \$350 000 to construct a hospital building of 146 bed capacity at the Veterans Administration Facility Lexington Ky to provide adequate hospital and outpatient dispensary facilities to care for veterans entitled to hospital care and treatment under the laws and regulations administered by the Veterans Administration H R 3214 introduced by Representative Geyer California proposes to authorize an appropriation of \$2 500 000 to construct a marine hospital at Los Angeles Harbor Los Angeles

## STATE MEDICAL LEGISLATION

## Alabama

*Bill Introduced*—H 56 proposes to require the governing body of each county to appropriate annually a sum equivalent to not less than 20 cents per capita of the population of such county, to be used for the maintenance and operation of a full time county health department under the direction of the county board of health and the county health officer and subject to the supervision and control of the state board of health

## Arkansas

*Bill Introduced*—H 101 proposes to prohibit the operation of a hospital unless licensed by the state board of health. The board is to be authorized to revoke the licenses of a hospital having 'sanitary conditions and ethical conduct' contrary in the opinion of the board to the best interest, safety and welfare of the people. The bill specifically provides that "The standard of ethics as adopted by the American Medical Association at date of passage of this Act is hereby adopted as a standard by which any hospital in this State shall operate"

## California

*Bills Introduced*—S 234, to amend those provisions of the Business and Professions Code stating the educational qualifications required of applicants for licenses to practice medicine, among other things, apparently proposes to make no differentiation with respect to requirements for licensure between graduates of Canadian medical schools approved by the board of medical examiners and graduates of approved American medical schools. A 531, to amend those provisions of the Business and Professions Code stating the educational qualifications required of applicants for licenses to practice chiropody, proposes that each applicant graduating from a chiropody college after Jan 1, 1941, present satisfactory evidence of having completed a one year resident course of 'pre-chiropodial work of college grade' in a school approved by the board of medical examiners before commencing the resident course of professional instruction. A 532 to amend those provisions of the Business and Professions Code relating to chiropody, proposes to make "Advertising free chiropodial services or examinations as an inducement to secure chiropodial patronage or advertising any amount as a price or fee for services" unprofessional conduct within the meaning of the code

## Georgia

*Bill Passed*—S 1 passed the senate January 20, proposing to create a state hospital authority to construct, operate and maintain self-liquidating projects embracing hospitals, sanatoriums, dormitories and housing accommodations and utilities and other facilities in connection therewith, at institutions under the control or supervision of any state agency or department. The authority is to be authorized to issue revenue bonds payable solely from the earnings and revenues of projects under the jurisdiction of the authority. A companion bill (H 1) has been introduced in the house

## Idaho

*Bill Introduced*—H 37 proposes to enact a cosmetology practice act and to create a state board of cosmetology to examine and license persons to practice cosmetology. Among other things, a licensed cosmetologist is to be authorized to remove superfluous hair from the body of any person by the use of depilatories or by the use of tweezers, chemicals, preparations or by the use of devices or applications of any kind or description

## Illinois

*Bill Introduced*—S 32, to amend the uniform narcotic drug act, proposes to redefine "cannabis" within the meaning of the act to include "all parts of the plant *Cannabis sativa* L., whether growing or not, the seeds thereof, the resin extracted from any part of such plant, and every compound, manufacture, salt, derivative, mixture, or preparation of such plant, its seeds, or resin, including specifically the drugs known as American hemp, marihuana, Indian hemp or hasheesh, as used in cigarettes or in any other articles, compounds, mixtures, preparations, or products whatsoever, but shall not include the

mature stalks of such plant, fiber produced from such stalks, oil or cake made from the seeds of such plant, any compound, manufacture, salt, derivative, mixture, or preparation of such mature stalks (except the resin extracted therefrom), fiber, oil or cake, or the sterilized seed of such plant which is incapable of germination"

## Indiana

*Bill Introduced*—H 78, to amend the narcotic drug act, proposes to redefine "cannabis" as to include "all parts of the plant *Cannabis sativa* L., whether growing or not, the seeds thereof the resin extracted from any part of such plant, and every compound manufacture, salt, derivative, mixture, or preparation of such plant, its seeds, or resin, including specifically the drugs known as American hemp, marihuana, Indian hemp or hasheesh, as used in cigarettes or in any other articles, compounds, mixtures, preparations, or products whatsoever, but shall not include the mature stalks of the plant, fiber produced from such stalks, oil or cake made from the seeds of such plant, any compound, manufacture, salt, derivative, mixture, or preparation of such mature stalks (except the resin extracted therefrom), fiber, oil or cake or the sterilized seed of such plant which is incapable of germination" This bill was reported favorably to the house on January 20

*Bill Passed*—H 37 passed the house January 25, proposing to appropriate \$75,000 annually for the biennium beginning July 1, 1939 with which the state board of health is to be authorized to purchase and to distribute free of cost to poor persons pneumococcus serum, diphtheria toxoid, smallpox virus and typhoid bacterins

## Iowa

*Bills Introduced*—S 28 proposes to require every physician attending a pregnant woman to take or cause to be taken a sample of her blood at the time of first examination and to submit that sample for standard serologic tests for syphilis to the State Hygienic Laboratory of the State Department of Health or to any laboratory approved by the department. H 30 proposes to require every person entering employment in any capacity in any food establishment to furnish the employer with a certificate of health and to furnish a similar certificate annually thereafter

## Kansas

*Bill Introduced*—H 44 proposes to enact a separate naturopathic practice act and to create an independent board of naturopathic examiners to examine and license persons to practice naturopathy. The bill proposes that any licensed naturopath may 'diagnose and treat diseases, injuries, deformities and other mental and physical conditions of human beings by means of the physiological and material sciences, such as physiotherapy, mechanotherapy, massage, corrective orthopedic gymnastics, neurotherapy, phytotherapy, hydrotherapy, psychotherapy, electrotherapy, thermotherapy, biochemistry, chromotherapy, vibrotherapy, thalamotherapy, dietetics, first aid, and such natural methods as are taught now or in the future in the approved naturopathic schools or colleges, to restore and maintain health" The bill specifically provides that nothing in it shall be construed to authorize any naturopath to administer or prescribe drugs or to practice surgery, osteopathy, chiropractic or Christian science

## Massachusetts

*Bills Introduced*—S 219, to amend the law prohibiting the operation of motor vehicles except by persons licensed to do so, proposes that each applicant for such a license be required to furnish a written certificate, after an acceptable medical examination, showing physical and mental fitness with a favorable intelligence rating. S 258 to amend the medical practice act, proposes that the term "practice of medicine" or "rendering medical service" shall include 'any examination or treatment of a human being, by the use or disuse of any means, for the purpose of diagnosing, preventing or curing any deviation from normal condition of mind or body or for the purpose of relieving any condition of mind or body whether arising from such a deviation or otherwise" H 985, to amend the medical practice act, proposes to provide that two members of the board of registration in medicine be osteopaths. H 986, to amend the medical

practice act, proposes that the approving authority vested with the right to approve schools from which applicants for licenses must be graduated shall consist of one doctor of medicine, one doctor of osteopathy, the commissioner of education and the commissioner of public health. The bill also proposes that the approving authority shall approve all medical schools which have the approval of the American Medical Association and all osteopathic schools which have the approval of the American Osteopathic Association, unless the decision to the contrary by the approving authority is unanimous on the part of all its members. H 1127 proposes to authorize the county commissioners of any county having a tuberculosis hospital to provide for the treatment of persons suffering from a disease other than tuberculosis when suitable accommodations are available. H 1221 to amend the workmen's compensation act, proposes that the employer's insurer shall pay to any nurse rendering nursing services in a hospital the rate of compensation prevailing in the city or town wherever such hospital is located.

#### Michigan

*Bill Introduced*—H 47, to amend the dental practice act, proposes to authorize the revocation or suspension of the license of any dentist "For advertising professional superiority or the performance of professional services in a superior manner, advertising prices for professional services, advertising by means of large display, glaring light signs, or containing as a part thereof the representation of a tooth, teeth, bridge work or any portion of the human head, employing or making use of advertising solicitors or free publicity agents, or advertising any free dental work, or free examination, or advertising to guarantee any dental service, or to perform any dental operation painlessly."

#### Minnesota

*Bill Introduced*—H 111 proposes to authorize the state board of control to establish a statewide system for the after-care of patients discharged from county and state tuberculosis sanatoriums.

#### New Mexico

*Bills Introduced*—H 13 proposes to enact a chiropody practice act and to establish a board of chiropody examiners to examine and license persons to practice chiropody. The bill proposes to define chiropody as "The diagnosis and the medical, surgical, mechanical, manipulative and electrical treatment of ailments of the human foot excepting amputation of the foot or toes or the administration of an anesthetic other than local." H 42, to amend the medical practice act, proposes to limit licensure to applicants who are citizens of the United States and who are graduated from medical colleges situated in the United States.

#### New York

*Bills Introduced*—A 279 and A 307 propose to enact a so called consumers protection act to prevent the manufacture and sale of adulterated or misrepresented drugs, foods, cosmetics or health devices and to regulate the traffic therein. S 180 and A 260 propose to authorize courts to enjoin persons engaging in the unlicensed practice of any profession for which a license and registration are required. A 269 proposes to make hospital records, or accurate copies thereof when certified by the officer in charge of the hospital admissible in courts as prima facie evidence of the contents thereof, provided that any declarations or statements made by the injured party of a nonmedical nature or which are explanatory or descriptive of the occurrence, happening or accident in question are not to be admissible. A 302 proposes to require a person engaged in the preparation, sale, inspection, supervision or handling of any food to submit to such examination including a standard serologic test as may be necessary for the discovery of syphilis, by a duly licensed physician at least once in every six months and to prohibit employment unless free of syphilis. A 218 and A 295 to amend the law requiring physicians attending a pregnant woman to take or cause to be taken a sample of her blood for a serologic test by an approved laboratory propose that a detailed report of the laboratory test, showing the result of the test shall be transmitted by the laboratory to the physician and that a copy of this report shall be submitted to the district state health officer or in a city of over 50,000 population or in a county health district to the department of health of such city or county.

#### North Dakota

*Bill Introduced*—H 113 proposes that "In all cases in which the Board of County Commissioners, State Welfare Board, or any other public board having supervision of poor relief shall provide medical assistance to indigent persons, such assistance shall be furnished by a Medical doctor, an Osteopath, a Chiropractor, or other legally licensed practitioners in the State of North Dakota, as requested by such indigent persons."

#### Ohio

*Bills Introduced*—S 28 proposes as a condition precedent to the issuance of a license to marry that both parties to the proposed marriage present physicians' certificate that they have been given such examination, including a standard serologic test made by a duly authorized representative of the state board of health as may be necessary for the discovery of syphilis, made on a day not more than twenty days preceding the date of application, and that, in the opinion of the physicians, the parties are not infected with syphilis. The bill proposes however that, if the woman is pregnant at the time of application for license to marry, the application be accepted without the certificate referred to being furnished by either party. S 22 proposes to create a commission to study, investigate and survey the possibilities for the rehabilitation of the visual and physically handicapped of the state. This commission is to consist of five persons named by the speaker of the house, five persons named by the president of the senate and three persons named by the governor.

#### Oklahoma

*Bill Introduced*—H 103 proposes that "Any regularly licensed physician or surgeon shall have the right to practice in any public or private hospital in this State, and the owner or manager of any such hospital who denies any such physician or surgeon from practicing in such hospital, or who refuses to admit any patient to such hospital because such patient desires to be treated by any particular physician or surgeon, upon conviction thereof shall be guilty of a misdemeanor."

#### Pennsylvania

*Bills Introduced*—S 12 proposes to require every physician who attends any woman pregnant with child to take or cause to be taken a sample of her blood at the time of the first examination and to submit that sample to an approved laboratory for a standard serologic test for syphilis. S 13 proposes to require as a condition precedent to the issuance of a license to marry that both parties to the proposed marriage present a statement signed by licensed physicians that both parties within thirty days of the application have submitted to examinations to determine the existence or nonexistence of syphilis, which examinations have included standard serologic tests for syphilis, and that in the opinion of the examining physician the applicants with syphilis or if so infected are not in a stage of that disease which may become communicable. H 28 proposes to prohibit the retail sale or distribution of sulfanilamide except on the written prescription of a licensed physician, dentist or veterinarian. A pharmacist is not to dispense any sulfanilamide without affixing to its container the label bearing the name and address of the pharmacist, the date compounded, the consecutive number of the prescription under which it is recorded in his prescription files and the name of the physician, dentist or veterinarian prescribing it. Physicians, dentists and veterinarians must keep a record of the amount of sulfanilamide purchased by them and dispensing records showing the dates on which and the names and addresses of patients to whom they have dispensed the drug and notations as to the quantity of the drug dispensed.

#### Wisconsin

*Bill Introduced*—A 55 to amend the workmen's compensation act, proposes to permit an injured employee to select at his employer's expense any physician, chiropractor or osteopath to attend him for his industrial injuries.

#### Wyoming

*Bill Passed*—H 18 has passed the house proposing that one member of the state board of health be a licensed dentist.

*Bill Introduced*—H 65 proposes to prohibit the sale of adulterated and misbranded cosmetics.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS REPLATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

### CALIFORNIA

**Mortality Rate in 1937**—There were 80,322 deaths registered in California in 1937, according to the state department of health. The death rate was 123 per thousand of estimated population, the highest for the state since 1928, when it was 125. Diseases of the heart and circulatory system led the list of causes of death with a total of 24,598. Cancer caused 8,670 deaths. There were 276 deaths attributed to whooping cough. Of the total number of deaths in the state, 71,295 were of members of the white race, 1,695 Negroes, 455 Indians, 545 Chinese, 620 Japanese, 5,257 Mexicans, 282 Filipinos and 173 of other races.

### COLORADO

**Society News**—The Mesa County Medical Society was addressed in Grand Junction December 20 by Dr. Edward L. H. Munro, Grand Junction, on silicosis. At a meeting of the Northern Colorado County Medical Society December 8, Dr. John V. Ambler, Denver, discussed 'Skin Conditions Affecting the Genitals'. Dr. William W. Haggart, Denver, discussed medical economics before the medical society, Sterling, January 12. At a meeting of the Fremont County Medical Society, Florence, December 19, Drs. Vardis A. Hutton, Florence, and Thomas A. Davis, Portland, discussed lobar pneumonia and bronchial pneumonia. The Pueblo County Medical Society was addressed in Pueblo January 17 by Drs. Charles Walter Metz and Clifford L. Hooper, Pueblo, on 'Newer Anesthetic Agents and Fupral Bursal Anesthesia with Cyclopropane' respectively.

### ILLINOIS

**Pictures of Physicians**—The Morgan County Medical Society recently sponsored an exhibit of more than 2,000 pictures of physicians and surgeons at the David Strawn Art Home, Jacksonville. The display also included about 1,000 pictures of medical subjects such as monuments and hospitals. The entire collection is the property of Dr. Carl L. Black.

**Society News**—Dr. Frederick W. Fitz, Chicago, addressed the Rock Island County Medical Society in Moline January 10 on "Heart Disease in Relation to Certain Manifestations of Nephritis". Dr. Willard Van Hazel discussed 'Treatment of Empyema' before the Kankakee County Medical Society in Kankakee January 12. At a meeting of the McHenry County Medical Society in Woodstock January 19, Dr. Philip H. Schneider, Evanston, spoke on 'Toxemia of Pregnancy'. The Will Grundy County Medical Society was addressed at Joliet January 18 by Dr. Robert B. Malcolm, Chicago, on hematuria. Dr. John A. Bigler, Highland Park, addressed the Ogle County Medical Society January 19 on 'Use of Sulfanilamide in Pediatric Practice'. Dr. Norman Tobias, St. Louis, discussed 'Treatment of the Common Dermatoses' before the Perry County Medical Society, DuQuoin, December 2.

### Chicago

**The Hektoen Lecture**—Dr. Eleonora T. Bell, professor of pathology, University of Minnesota Medical School, Minneapolis, will present the fifteenth Ludvig Hektoen Lecture of the Frank Billings Foundation at the Palmer House February 24. He will discuss 'The Pathogenesis of Glomerulonephritis Including Lipoid Nephrosis'.

**Medicodental-Military Training Course**—The second Chicago medicodental-military training course will be held February 26-March 11. Attendance is not restricted to those from the Chicago area. Requests for additional information concerning the course should be addressed to the commanding general, sixth corps area, Post Office Building.

**Personal**—Dr. John R. Neal, Springfield, has been appointed dean of the Cook County Graduate School of Medicine. Dr. Neal is secretary of the Illinois Professional Committee for Medicine, state department of registration and education and formerly served as president of the state medical society. He graduated at Northwestern University Medical

School in 1909. Miss B. Fain Tucker, an attorney, has recently written a comprehensive article entitled "Social Health Laws" in which she reviews existing legislation concerning the issuance of licenses to marry from a health point of view.

### MAINE

**Society News**—At the annual meeting of the Oxford County Medical Society in Bethel recently, Dr. Gilbert E. Haggart, Boston, among others, discussed some problems in bone and joint surgery. Dr. Maxwell E. Macdonald, Boston, addressed the Cumberland County Medical Society in Portland December 9 on 'Emotions and Bodily Changes'. At a meeting of the Portland Medical Club December 6, Dr. Edwin W. Gehring, spoke on 'The Interrelation Between Medicine and General Economics'. Dr. Albert Warren Stearns, Boston, discussed medicolegal problems before the Kennebec County Medical Association in Augusta December 15. At the annual meeting of the Waldo County Medical Society in Belfast January 26, Dr. Charles B. Popplestone, Rockland, spoke on electrocardiography.

**Graduate Fellowships in Obstetrics and Gynecology**—The Bingham Associates Fund is offering fellowships in obstetrics and gynecology to practicing physicians of Maine, the work to be conducted under the supervision of the faculty of Tufts College Medical School. The facilities of the New England Medical Center, the Joseph H. Pratt Diagnostic Hospital, the Poston Dispensary and the Evangeline Booth Maternity Hospital, Boston, will be utilized. The fellowships are for one month each and are available to graduates of approved medical schools. Each fellowship carries an honorarium of \$250. Rooms and meals are available to fellows at reduced rates in the medical center. Additional information may be obtained from Dr. Samuel Proger, 25 Bennett Street, Boston, Dr. Frederick R. Carter, Augusta, or Dr. Frederick T. Hill, the Professional Building, Waterville.

### MASSACHUSETTS

**Society News**—The Greater Lawrence Medical Association held its first annual dinner in Methuen November 17 with Dr. John F. Curtin, Lawrence, as toastmaster. The speakers included Drs. Charles F. Mongan, Somerville, formerly president of the state medical society, and Frank H. Lahey, Boston. Organized Dec. 12, 1933, the society's membership is made up of physicians in Lawrence, Methuen, North Andover, Andover, Mass., and Salem, N. H.

**Annual Meeting of Gynecologists**—The tenth annual meeting of the New England Obstetrical and Gynecological Society was held in Boston in December under the presidency of Dr. Bertram H. Buxton, Providence, R. I. Clinics made up a large part of the program and papers were delivered by the following, among others:

Dr. Somers H. Sturgis, Treatment of Dysmenorrhea with Estrin.  
Dr. Joe V. Meigs, The Technique of Total Hysterectomy and Its Use in Patients with Cystocele and Urolyse.  
Dr. Charles Langdon Parsons, Endometriosis.  
Dr. Marshall K. Bartlett, Recent Vitamin C Studies.  
Dr. Ward I. Gregg, Demonstration of the Samuels Apparatus to Detect Ovulation.  
Dr. Edward B. Benedict, Peritoneoscopy.  
Dr. Fuller Albright, Treatment of Ovarian Insufficiency.  
Dr. Oliver Cope, Experiences with Adrenal Tumors.

### MICHIGAN

**Adjusters Medical Committee**—A joint committee, composed of representatives of the Wayne County Medical Society and the Detroit Adjusters Association, has been established for discussions and cooperative studies designed to correct the causes of complaints and to eliminate such abuses as may be current and particularly to remove friction from the several interests represented on a voluntary basis and without necessity of resorting to mandatory measures. Members of the committee are Drs. Howard B. Garner, chairman, Earl G. M. Krieg and Frank T. McCormick, and Messrs. L. J. Carey, E. Dean Alexander and William H. Heidt.

**Changes in State Health Department**—Dr. Richard Sears, epidemiologist with the Michigan State Department of Health and recently acting director of the Muskegon County health department, has been appointed director of health district number 5, including Lake Newaygo and Oceana counties, succeeding Dr. Guy R. Post who resigned. His headquarters will be in White Cloud. William E. Bunney, Ph.D., director of the biologic products division of the state department of health for seven years, has resigned to become director of biologic products for E. R. Squibb & Sons, New Brunswick, N. J. George F. Forster, Ph.D., Lansing, who has been

engaged in research on pneumonia for the department during the past two years, has resigned to become assistant director of the laboratories of the Illinois State Department of Health, Springfield, according to the state medical journal

## MISSOURI

**Lectures on Tuberculosis**—The Missouri Tuberculosis Association is sponsoring a series of lectures for colleges in the state. Speakers at the Central Missouri State Teachers College, Warrensburg December 13-15 were Drs Paul A. Teschner, assistant director Bureau of Health Education American Medical Association, Chicago, on "The History of Tuberculosis" Herbert L. Mantz, Kansas City, Treatment and Diagnosis of Tuberculosis and Jesse E. Douglass, Webb City, 'Sociology and Tuberculosis'.

**Society News**—Dr Warren H. Cole Chicago discussed 'Late Advances in Diseases of the Pancreas' before the Kansas City Academy of Medicine December 16—Dr Walter Roger Moore discussed 'The Treatment of Toxicity of Snake Bite' before the Buchanan County Medical Society in St. Joseph January 4—The Chariton County Medical Society was addressed in Salisbury recently by Drs Arthur Lloyd Stockwell and Paul C. Quistgard, Kansas City on Clinical Interpretation and Management of Pyuria and Hematuria and Intestinal Obstruction respectively.

**Cornerstone Laid for Cancer Hospital**—The cornerstone of the Ellis Fischel State Cancer Hospital, Columbia was laid with suitable exercises December 9. The speakers included Mr Frank T. Hodgdon chairman of the state cancer commission who presided Lloyd Crow Stark, governor of Missouri and Clarence C. Little D.Sc. Bar Harbor Maine. The hospital is named for the late Dr Ellis Fischel first chairman of the commission. Dr Fischel was instrumental in the passage of the bill by the fifty ninth general assembly of Missouri which created the cancer hospital and instituted the program for cancer control in the state. The bill also established the cancer commission and provided for the formation of various diagnostic tumor clinics throughout the state. The hospital will occupy a forty acre site donated by the city of Columbia. It will cost about \$900,000 the state appropriating \$500,000 and the PWA the remainder. The building will consist of seven stories and a penthouse offering an approximate capacity of eighty-three beds.

## NEW JERSEY

**Tuberculosis Meeting in Jersey City**—A clinical session of the Tuberculosis Sanatorium Conference of Metropolitan New York will be held at the Hudson County Tuberculosis Hospital Jersey City, February 15 with the following speakers: Drs Frank C. Henry Jr, Perth Amboy, on 'End Results in Thoracic Surgery with the Use of Ultra-violet Radiation' Thomas de Cécio Secaucus, Management of Nonpyematous Pleural Effusions Complicating Artificial Pneumothorax and Paul Geary Plainfield Extrapleural Pneumothorax.

**Society News**—Dr John J. H. Keating New York addressed the Bergen County Medical Society Englewood January 10 on Background and Newer Aspects of Coronary Diseases—Dr John A. Kolmer, Philadelphia addressed the Essex County Anatomical and Pathological Society Newark January 26 on The Toxicity and Therapeutic Applications of Sulfanilamide. Dr Reuben Ottenberg New York opened discussion—At a meeting of the New Jersey Neuro-Psychiatric Association December 14 Dr Ambrose F. Dowd Newark was reelected president. Dr Laurence M. Collins Greystone Park was elected vice president and Dr Henry A. Davidson, Newark, secretary.

## NEW YORK

**Court Upholds Refusal to Endorse Foreign License**—The appellate division of the Supreme Court of New York handed down a decision January 11 upholding the refusal of the Board of Regents of the University of the State of New York to endorse the Italian license or diploma to practice medicine of Dr Gustave G. E. De Luca. The board refused to endorse the license on the ground that there is great uncertainty as to whether the standards of the European institutions today are comparable to what they were when the law was enacted which gives the commissioner and the board of regents authority to endorse foreign licenses without examination. The board offered the petitioner in this case the opportunity to take the licensing examinations.

## New York City

**Hospital News**—Dr George G. Ornstein delivered the Pol N. Coryllos Memorial Lecture on Thoracic Diseases at the Manhattan General Hospital January 9 on 'Classification and Management of Pulmonary Tuberculosis'—Dr Otto Marburg, formerly professor of neurology at the University of Vienna gave a lecture at Mount Sinai Hospital January 24 on 'Hydrocephalus Clinical Manifestations Pathogenesis and Therapy'.

**Women Physicians' Meeting**—The semiannual meeting of the Women's Medical Society of New York was held January 7-8. At the scientific session the first day at Lenox Hill Hospital the speakers were Drs Margaretha A. Ribble on 'The Relation of Infant Nurture to Mental Health' Frances L. H. Bogatko 'Five Year Follow-Up to Fifty Cases of Varicose Veins Treated by Injection', Mary M. Thomson 'Difficulties of Parents in Understanding Their Children' and Martha Theresa Scanlan 'Recent Advances in the Treatment of Pulmonary Tuberculosis'.

**Meeting on Pneumonia**—At a meeting of the section on medicine of the New York Academy of Medicine January 17 Dr Yale Kneeland Jr spoke on 'Pneumonias Other than Pneumococcus Pneumonia' and a group of speakers reported on the use of sulfapyridine in the treatment of lobar pneumonia. The speakers were Herbert E. Stokinger on 'The Absorption Acetylation and Excretion of Sulfapyridine' Drs Norman H. Plummer and Herbert K. Emsworth representing New York and Bellevue hospitals. Colin M. MacLeod Rockefeller Institute Charles A. Ragan Jr and Crispin Cooke Presbyterian Hospital, and Ezra B. Sanford Roosevelt Hospital. Drs Alphonse R. Dochez and Jesse G. M. Bullowa discussed the contributions.

## NORTH CAROLINA

**Conference on Maternal and Child Health**—A State-wide Conference on Better Care of Mothers and Babies will be held in Raleigh February 15 under the auspices of the National Council for Mothers and Babies and the North Carolina State Board of Health. There will be symposiums on 'Safeguarding the Infant and Young Child and Reduction of the Hazards of Childbirth to the Mother and Baby' in the morning. In the latter symposium Dr Edum F. Dail of the U. S. Children's Bureau Washington D. C. will be a guest speaker. Among other guests will be Drs Fred L. Adair Chicago chairman of the American Committee on Maternal Welfare, and Martha M. Lhot Children's Bureau Washington. Dr F. Bayard Carter professor of obstetrics and gynecology, Duke University School of Medicine Durham will summarize the discussions at the end of the day. Dr Aldert S. Root Raleigh chairman of the North Carolina section of the American Academy of Pediatrics will be chairman of the conference.

## OHIO

**Public Health Lectures in Cleveland**—The ninth annual series of free public health lectures sponsored by the Academy of Medicine of Cleveland, the Albert Fairchild Holden Foundation and the Cleveland Medical Library Association will begin February 12 with a lecture by Dr Howard Dittich on 'Getting Ready for Married Life'. The succeeding lectures will be presented by Drs Neil F. McDermott February 26 on 'Adjustments of Married Life' and Chauncey W. Wyckoff March 12 on 'The Young Age Child'.

**Personal**—Dr George W. Cline Cleveland with Mrs Cline and Daniel P. Quiring Ph.D. assistant professor of biology at Western Reserve University School of Medicine recently undertook an expedition to Guatemala to study animals in pursuit of information on comparative anatomy. In addition they will make measurements of metabolism on primitive Indians in Guatemala. The trip is sponsored by the Cleveland Clinic Foundation—Dr Earl Crafts has resigned as psychiatrist at the Luna State Hospital to enter private practice—Dr Roland A. Willett Elmore was honored by the Ottawa County Medical Society recently with a testimonial dinner in Danbury celebrating his fiftieth anniversary in the practice of medicine—Dr Frederick C. Smith Marion was elected to the national House of Representatives from the eighth district in the November election. Dr Loret Le Fevre Gloucester was elected to the state house of representatives and Dr Henry T. Phillips Athens to the state senate—The Jefferson County Medical Society gave a dinner in honor of Dr Silas O. Barkhurst Steubenville November 3 in Steubenville celebrating his fiftieth anniversary of medical practice. Dr Fred M. Shugher Steubenville was toastmaster.

## OKLAHOMA

**State Society Appoints Executive Secretary**—At a meeting of the council of the Oklahoma State Medical Association December 11 Mr. R. H. Graham, Peabody, Kan., was appointed executive secretary to take office January 1. His office will be in McAlester with the secretary of the state association, Dr. Leonard S. Willour. Mr. Graham will immediately visit several states to study methods of executive secretaries.

## PENNSYLVANIA

**Diabetes Commission Formed**—At the recent annual meeting of the Medical Society of the State of Pennsylvania in Scranton a commission on diabetes was formed with Dr. Belford C. Blaine, Pottsville, as chairman and representatives of all the councilor districts as active members. Drs. David W. Thomas, Lock Haven, president of the state society, Charles H. Henninger, Pittsburgh, president elect, and Walter F. Donaldson, Pittsburgh, secretary of the state society and Dr. Edward L. Bortz, Philadelphia, are ex officio members. The commission plans to make an intensive study of the incidence and mortality from diabetes, the complications, facilities for treatment and the facilities for education of physicians. It hopes to disseminate knowledge to the public as well as to physicians, nurses and technicians. At the same time the commission was formed as an agency of the state society, a diabetic society was organized with Dr. Joseph T. Beardwood, Jr., Philadelphia, as president and Dr. Blaine, Pottsville, as secretary.

## RHODE ISLAND

**Society News**—Dr. Albert Warren Stearns, Boston, addressed the Providence Medical Association January 9 on "The Evolution of the Concept of Functional Nervous Diseases." Mr. Myron Weiss, associate editor of *Time*, New York, and Dr. David R. Lyman, Wallingford Conn., addressed the association at its December meeting on "The Future Pattern of Medicine" and "Early Diagnosis of Tuberculosis" respectively. The association has recently added the presentation of a weekly radio program to its activities.

## VIRGINIA

**State Board Appointment**—Dr. William B. McIlwaine III, Petersburg, has been appointed to the state board of medical examiners to succeed the late Dr. Fletcher J. Wright, Petersburg, it is reported. The appointment is for four years.

**Society News**—"The National Health Program and Medical Care" was the subject of discussion at the quarterly meeting of the Augusta County Medical Society recently in Staunton. Among the speakers were Drs. Hugh H. Trout, Roanoke, president-elect of the Medical Society of Virginia, and Walter B. Martin, Norfolk, chairman of the committee on medical economics of the state society.—Dr. Hamilton W. McKay, Charlotte, N. C., among others, addressed the Roanoke Academy of Medicine recently on pediatric urology.—Drs. John A. Kolmer, Philadelphia, and Cecil S. O'Brien, Iowa City, addressed the Richmond Academy of Medicine recently on "Toxicity and Therapeutic Applications of Sulfanilamide" and "Common Causes of Loss of Vision" respectively.—Speakers at a meeting of the South Piedmont Medical Society in South Boston recently included Drs. Hugh H. Trout, Roanoke, on "Posthospital Care of Surgical Patients", Kinloch Nelson, Richmond, "Diagnosis and Treatment of Aortic Syphilis," and Flavius O. Plunkett, Lynchburg, "Obstetric Analgesia and Anesthesia."

## GENERAL

**Examination Date Changed**—The American Board of Pathology announces that it has changed the date of its next examination from April 8-9 to April 3-4.

**Congress on Military Medicine**—The tenth International Congress of Military Medicine and Pharmacy will be held in Washington, D. C., May 7-15, with headquarters at the Hotel Willard. Major Gen. Charles R. Reynolds, surgeon general, U. S. Army, is president of the congress and the secretary general is Col. Harold W. Jones, Army Medical Library, Washington, to whom all communications should be addressed. Questions listed for discussion at the congress are organization and function of the medical services in colonial expeditions, probable casualties in war and methods of calculation, practical procedures for anesthesia and analgesia in war surgery, organization and function of the military chemico-pharmaceuti-

cal service, emergency treatment and primary apparatus for fractures of the jaw in war, technical specialization of administrative officers in the medical service and oxygen therapy and its practical use with troops on active service.

**Physicians' Art Association**—The American Physicians' Art Association, composed of members in the United States, Canada and Hawaii, will hold its second art exhibition in the Museum of Art, St. Louis May 14-20, during the annual session of the American Medical Association. In order to submit art pieces to this exhibition each exhibitor must become a member of the American Physicians' Art Association. For details of membership and exhibition rules write to Dr. Max Thorek, secretary, 850 Irving Park Boulevard, Chicago, or Dr. Francis H. Redewill, president, 870 Market Street, San Francisco.

**Mid-South Graduate Assembly**—The fifty-fourth annual session of the Mid-South Post Graduate Assembly will be held at the Hotel Peabody, Memphis, Tenn., February 14-17. There will be twenty-seven speakers, among whom are the following:

Dr. Norris W. Vaux, Philadelphia, Puerperal Sepsis  
Dr. Dean M. Tierle, Iowa City, The Causes of Hoarseness  
Dr. Leon J. Menville, New Orleans, Irradiation Therapy in Diseases of the Glands of Internal Secretion  
Dr. William P. Herley, New York, Carcinoma of the Cervix Uteri  
Problems of Diagnosis  
Dr. Edward B. Shaw, San Francisco, The Evaluation of Methods for Immunization  
Dr. Anthony Bessler, New York, The Pathologic Gallbladder: What Causes It and What to Do With It  
Dr. Saml Weiss, Boston, The Importance of Differentiation of Failure of the Peripheral Vascular System from Heart Failure  
Dr. Julius H. Hess, Chicago, The Premature Infant  
Dr. Frederick A. Collier, Ann Arbor, Mich., Peritonitis

**Birth Rate Declines with Urbanization**—Birth rates have decreased most rapidly in the past ten years in states in which the population is concentrated in urban areas according to a study reported in the *Statistical Bulletin* of the Metropolitan Life Insurance Company. A block of states from New England to Nebraska containing 50.2 per cent of the whole population of the country, showed decreases of 10 per cent or more. They include New Hampshire, Massachusetts, Rhode Island, Connecticut, New Jersey, New York, Delaware, Maryland, Virginia, Pennsylvania, Ohio, Indiana, Illinois, Missouri, Arkansas and Nebraska. All the next group with decreases of from 5 to 9 per cent in the birth rate are east of the Mississippi except California, Kansas and North Dakota, in this group is found 25.9 per cent of the nation's population. Five sparsely settled and essentially rural mountain states—Montana, Idaho, Nevada, Arizona and New Mexico—with Mississippi, recorded higher rates for the ten years. It is apparent then, the report pointed out, that the country's population growth depends on its rural nonindustrialized element. "With this situation confronting us, it is obvious that our rural areas will need the guidance of child welfare and maternal aid agencies more than ever before if they are to continue as our chief source for population growth," the bulletin concluded.

**Northwest Regional Conference in Chicago**—The Northwest Regional Conference will be held at the Palmer House, Chicago, Sunday February 12, with Dr. Carl F. Vohs, St. Louis, chairman of the Committee on Medical Economics of the Missouri State Medical Association, as president, and Dr. L. Fernald Foster, Bay City, Mich., secretary of the Michigan State Medical Society, as secretary. Beginning at 10 a. m. in the Red Lacquer Room, Dr. Major G. Seelig, St. Louis, will discuss "A State-Wide Hospitalization Plan for the Low Income Group", Dr. Walter F. Donaldson, Pittsburgh, "Pennsylvania's Public Assistance Program for the Medically Indigent", Drs. Donald A. Covall, Joseph C. Silvers and Lall G. Montgomery, Muncie, Ind., "Middletown Modernizes Medicine (lantern slides)", Dr. Theodore R. Meyer, Clayton, Mo., "The Physician's Role in a Public Health Program."

The Missouri State Medical Association will be host to the representatives from other state medical associations at a 1 o'clock luncheon, at which Dr. Vohs will make a report. The election of officers will follow.

At 2 p. m. Dr. Henry A. Luce, Detroit, will discuss "The National Health Conference". Dr. William F. Braasch, Rochester, Minn., will survey on the Need and Supply of Medical and Hospital Care, Dr. Rosco G. Leland, Chicago, "Supplementary Arrangements for Medical Care", and Mr. Clarence G. Munns, Topeka, Kan., "Kansas Can Control Cultists". All presentations will be open to general discussion.

## Government Services

### Annual Report of Public Health Service

In his annual report for the fiscal year ended June 30, 1938, released January 8, the Surgeon General, U S Public Health Service, states that the general death rate for the calendar year 1937 was 109 per thousand of population as compared with 113 for the preceding year. This favorable condition continued in 1938, when preliminary figures for the first six months disclosed a mortality rate of 108 per thousand as compared with 118 for the corresponding period of 1937.

There was a decrease in infant mortality from 571 per thousand live births for 1936 to 544 in 1937. The maternal mortality rate continued to decline, 4.6 per thousand live births in 1937 against 5.3 during 1936.

The tuberculosis mortality resumed a downward course after a slight increase in 1936. The improvement was apparent in the provisional tuberculosis death rate, which declined from 51.7 per hundred thousand population in 1936 to 49.6 in 1937.

During 1937 lowered death rates were reported for typhoid fever, scarlet fever, diphtheria, tuberculosis, malaria, pellagra, nephritis and puerperal causes. During 1937 a total of 11,673 cases of smallpox was reported, as compared with 7,834 in 1936 and 7,957 in 1935. The number of reported cases in 1937 was the highest since 1931. The prevailing smallpox is of a nonvirulent type, causing relatively few deaths.

The United States suffered minor epidemics of influenza and poliomyelitis in 1937. The number of cases of poliomyelitis, 9,511, has been exceeded only in four previous years for which records are available, 1916, 1927, 1931 and 1935.

The leading causes of death in 1937 were diseases of the heart, cancer and other malignant tumors, pneumonia, cerebral hemorrhage and softening, nephritis, accidents (except automobile) and tuberculosis.

The U S Public Health Service inspected at ports of entry 1,784 airplanes carrying 23,172 passengers and 15,873 vessels carrying 789,591 passengers and 1,196,688 seamen. Fumigation of 1,004 vessels was performed and 5,399 rats were examined for evidence of plague infection. Medical officers at various United States ports of entry inspected 2,447,339 alien passengers and 805,306 alien seamen. Of these, 20,372 passengers and 1,438 seamen were reported as having some certifiable disease or defect. In foreign countries 65,261 applications for immigration visas were examined.

The most important event in the campaign against the venereal diseases during the fiscal year was the enactment by Congress of the Venereal Disease Control Act, whereby facilities for the more effective control of syphilis and gonorrhea were placed on a permanent national basis. Congress appropriated \$3,000,000 to assist states in establishing and maintaining measures for the prevention, control and treatment of venereal diseases. The use of Social Security funds for the training of physicians in the clinical management and public health control of the venereal diseases was continued in several universities and clinics. The experimental control of syphilis among indigent people of rural areas was demonstrated by the use of a trailer clinic in Georgia. A study of untreated syphilis in a group of male Negroes was continued. Measures designed to control syphilis in industry were inaugurated.

The Public Health Service continued to supervise and furnish medical, psychiatric, technical and other scientific services to federal and penal institutions. Special studies were conducted in cooperation with the Mental Hygiene Survey Committee to stimulate interest in the adequate care of the mentally ill, bring about greater equality and wider distribution of facilities, promote uniform policies and improve the facilities for psychiatric instruction.

The twenty-seven hospitals of the Public Health Service engaged in the care and treatment of legally designated beneficiaries and also in scientific clinical research, furnished hospital and outpatient relief at 154 ports where 566,931 accredited persons applied for treatment. This represents an increase of 211,121 patients over the preceding year. Merchant seamen continued to constitute the largest class of beneficiaries. Research was continued in pyretotherapy, focal infections, arthritis and psoriasis.

The erection of specially designed structures for the National Institute of Health near Bethesda, Md., makes available increased facilities for scientific research. Continued attention was directed to the control of biologic products, particularly antipneumococcal rabbit serum and antimeningococcal serum, and close supervision over the stability of antiphthalmine.

In the field of industrial hygiene, investigations were directed to the development of means for the protection and the improvement of the health of workers in various fields of industry.

The activities of the National Institute of Health, comments the Surgeon General, are becoming increasingly numerous. Thus, one group of workers is engaged in chemical research while another is directing its attention to studies of such infectious diseases as Rocky Mountain spotted fever, typhus, scarlet fever, Weil's disease, leprosy and poliomyelitis. A special series of investigations have shed considerable light on the various phases of trichomonis infection. Clinical epidemiologic and laboratory studies of heart disease, especially the rheumatic type, have produced valuable information.

The interesting discovery was made that fluorides, which cause mottled enamel, may be removed from drinking water by treatment with manganese dioxide, a method which gives promise of economical development.

A firm basis for future cancer studies is being laid through grants in aid to selected institutions and the training of research specialists.

Every state and many cities, as well as every department and independent agency of the federal government, has received some degree of assistance from the Public Health Service in solving special health problems arising in the course of routine operations. This cooperative work is carried on principally by the division of states relations.

The availability of funds under the provisions of the Social Security Act has made it possible to assist in improving state and local health administration. From Jan. 1, 1935, to December 1937 there was an increase in full-time health units of 96 per cent. Facilities for the promotion and supervision of such full-time facilities have been developed in nineteen states.

Stimulated by federal grants in aid, the state and local appropriations for public health purposes have increased \$8,000,000 annually.

Cooperation was continued with the states and the Works Progress Administration by providing technical supervision of work relief labor projects for the construction of sanitary toilets, malaria control drainage in the South and sealing of abandoned coal mines. Certification of water supplies used by interstate carriers, a valuable measure in preventing water-borne illness, continued without interruption.

In closing, the Surgeon General recommended among other essentials the establishment in the National Institute of Health of a unit for wider chemotherapy investigations, additional funds under the Venereal Disease Control Act on an increasing scale until an annual appropriation of \$25,000,000 is reached, and the establishment of a neurologic institute for laboratory and clinical investigations of mental and nervous diseases.

### CORRECTIONS

**Returns Under the Social Security Act**—The statement in the organization section of *THE JOURNAL*, January 14, page 153, that a tax return with respect to federal old age benefit taxes is required every month, on form SS-1, was incorrect. Such returns are required quarterly on form SS 1A.

**Appointed Assistant Superintendent**—Dr. Raymond J. Gully, formerly senior physician at the Minnesota St. Peter State Hospital, St. Peter, has been appointed assistant superintendent at the Minnesota Colony for Epileptics, Cambridge. Instead of superintendent as reported in *THE JOURNAL*, January 21, page 250. The news item originally appeared in *The Journal Lancet*, October 1938, page 461.

**Sulfanilamide Omission of "not"**—In the paper by Long Bliss and Feinstein in *THE JOURNAL*, January 14, page 119, second column in the sentence beginning in the thirteenth line from the bottom, the word "not" should be inserted so that the sentence reads "Marshall and Walz express the opinion that the formation of methemoglobin is not always responsible for the cyanosis."

**Study of Medical Care**—The executive secretary of the Ohio State Medical Association has called attention to the following statement in the Ohio State Medical Association Report on the Study of Medical Care in the organization section of *THE JOURNAL*, January 21, page 243: "Legislative appropriations however have been insufficient to meet the hospital's operating expense, this condition has necessitated a reduction in the number of pay patients admitted." The exact statement in the original report was: "Legislative appropriations have been insufficient to meet the hospital's operating expense. This has necessitated the admittance of pay patients."

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Jan 7, 1939

#### The Medical Uses of Radium

The sixteenth annual report of the Medical Research Council on the medical uses of radium reflects the increasing importance of experimental work.

#### NEUTRONS

Professor Hopwood is investigating the physicochemical effects of neutrons (particles of unit atomic weight 1 but carrying no electrical charge) and gamma rays. He has established that the effects of neutrons are of the same nature as those of the gamma rays but far more powerful and that negatively charged colloidal particles become more stable and positively charged colloids less stable when irradiated with either neutrons or gamma rays. Over a wide range of exposures the breakdown of dilute aqueous solutions of hydrogen peroxide and the oxidation of dilute solutions of potassium metabisulfite were directly proportional to the number of neutrons captured or the amount of gamma ray energy absorbed. His experiments support the view that the primary action of the radiations is on water, which suggests that the part played by water in the animal body is more important than has been supposed.

#### THE TREATMENT OF CANCER

At the Marie Curie Hospital, cancer of the corpus uteri has been treated by operation when possible and radiation has been reserved for cases in which operation was contraindicated or declined. But irradiation has given results which suggest that after all this may be the best treatment in all cases of cancer of the corpus except when the cancer is complicated by myomas or ovarian tumors or possibly when pelvic inflammatory disease is present. The five year survival rate is found to be the same for radiotherapy as for operation while the distress to the patient is much less.

Cancer of the esophagus is treated at the Middlesex Hospital by radon mounted on Souttar's tubes a dose of 3000 roentgens being given in five days, during which the patient is fed by a stomach tube passed through the nose and the Souttar tube. This procedure improves the general health, avoids the need for gastrostomy and relieves the dysphagia during subsequent roentgen therapy, which is still considered to be the best treatment.

#### RADIOTHERAPY IN METRORRHAGIA A WARNING

The Marie Curie Hospital issues a warning as to the radiotherapy of metrorrhagia in young women. The report points out that irradiation has produced abnormalities in the offspring of animals. This suggests that gene mutations may be produced in the young. As only one generation has passed since radiotherapy has been used extensively, sufficient data are not yet obtainable as to the effect on human offspring. It is important that all women of child-bearing age receiving radiotherapy be kept under observation and their descendants followed up.

#### The Value of a Surgeon's Finger Tip

The value to a surgeon of his finger tip has been the subject of judgment in a law court. Mr Hett, a London laryngologist, while on a vacation in Scotland hired an automobile for a drive. On alighting he placed his right hand on the center post of the front door in order to assist his wife, who was lame, to get out. The driver slammed the door, catching Mr Hett's right middle finger across the nail between the flange and the post and severing the bone. He brought an action for \$10,000 against the proprietress of the car for the

negligence of the driver. In the Edinburgh court of session the judge, Lord Keith, held that the driver should have looked to see that the passenger's hand was not in danger before he shut the door. His failure to do so amounted to negligence. The surgeon had suffered permanent disfigurement and loss of sensitiveness of his finger tip. Being a specialist in ear and throat surgery, he would suffer from the loss, particularly in tonsil cases. He might be unable to undertake some of the more difficult throat operations and have to rely on an assistant more than formerly. The judge had difficulty in assessing damages. Mr Hett was now 60 and he admitted that he intended to retire at 70, but he produced no figures to show his earnings during the year. The judge awarded \$3,000 damages, a little over a third of the claim.

#### London Jewish Medical Society

The eleventh annual dinner of the London Jewish Hospital Medical Society was held in London, with Prof Henry Cohen of Liverpool in the chair. The guest of honor was Dr Robert Hutchinson, president of the Royal College of Physicians, who said that he was glad to be honored by a society in which he had so many friends and whose members belonged to a race to which the science of medicine owed so much. In proportion to its numbers no race had contributed so freely to medicine especially during the last fifty years. The Jews and the Scots (of whom he is one) had many qualities in common such as devotion to education, awareness of the value of hard work and a capacity for getting on. We fear God and push him said. He suggested that both Jews and Scots were real strangers in England and should always remember that they were the guests of a kindly and tolerant people.

The society and its president was the toast proposed by Mr R. Scott Stevenson, in whose opinion too great limitations should not be imposed on the number of Jewish physicians admitted from central Europe. Replying on behalf of the society the ophthalmologist Mr Arnold Sorsby said that the persecution of the Jews was not a specifically Jewish problem but had its wider aspect: it was essentially an attack on the dignity of human life. An appeal was made on behalf of the refugees.

#### Protest Against Inroads of Social Insurance and Competition of Public Hospitals

Attention was called in a letter in THE JOURNAL Dec 10 1938 to a protest meeting in Paris November 4 under the auspices of the medical syndicate or organization which has charge of public relations of the physicians practicing in Paris and its suburbs. More than 1500 practitioners attended the meeting. The president, Dr Boelle, said that practitioners with few exceptions are at present unable to earn a living. This affects recently licensed as well as older men, as shown by the number of appeals for aid from members of the syndicate. This state of affairs is a danger, because it is liable to tempt physicians to abandon the ethical methods so long upheld by the profession. Not only has the average practitioner's income been reduced but his expenses have been increased by excessive taxation and the rise in the cost of living. The department of the Seine, in which Paris is located, contains one eighth of the entire population of France and one fourth of all French practitioners. Many foreign physicians have come to France since the World War, thus adding to the competition. Another cause of the sad plight of the practitioner is the free rein given to quackery of all types. In few other countries does the press allow as much space to be occupied by advertisements of all sorts of cures. So far the medical profession has not been successful in its efforts

to suppress such practices, but some hope will be held out if proposed laws are passed

These two causes of the present depression are of minor importance compared with the major one of collective medicine as it is being practiced all over France, but not so seriously affecting the country practitioners as it does their city colleagues. A large percentage of patients, instead of consulting a physician at his office or calling him to attend them at their homes, apply for medical aid to the hospitals of the city of Paris, dispensaries of all kinds, social insurance bureaus and the organizations established by various industrial concerns. The city hospitals made no discrimination in their admission of patients. Many patients from country districts, by giving false addresses, are admitted although well able to pay for care in private institutions. It is estimated that 22 per cent of the patients in public hospitals would be refused admission if inquiries were made as to their financial status. Many patients prefer to go to a city hospital because the staffs are composed of some of the most eminent members of the profession, who are appointed after a severe competitive examination. A bill is now before the parliament which will enable a stricter control to be maintained against admission of those who are able to pay for medical aid.

A final cause of the present sad lot of the practitioner is the social insurance organization. The indemnities allowed for sickness and maternity claims have been so insignificant that it has resulted in the insureds being forced to apply to dispensaries and city hospitals instead of consulting practitioners and going to private hospitals. The insured receives only 15 francs (35 cents) from the *caisse* or social insurance office, but is obliged to pay twice as much for consulting a physician. Even if the patients go to a physician's office or call him to their homes, the *caisses* compel a great many formalities to be fulfilled and pay only after much argument.

#### Sulfanilamide in the Prevention of Puerperal Infection

Before receiving a state license, every medical student in France is obliged to submit a thesis based on clinical or research problems. Dr. Guy Picot chose as the subject of his thesis a review of the effort now being made at the Tarnier Maternity Hospital of Paris to use sulfanilamide as a prophylactic in the prevention of puerperal infection. The observations included in the thesis cover a year, the drug being given only to women at or near term. Every pathologic case was excluded from the first series to forestall any criticisms. For every patient to whom the drug was given, another was kept under observation as a control, not receiving any medication. The treatment was begun four days before labor, the total dose being 16 Gm., and four days after delivery the same total dose was given. Of 1,175 patients, 479 were given sulfanilamide and 696 used as controls. A puerperal infection occurred in fifteen or 3.13 per cent, of the 479 receiving treatment but there were no deaths. Of the 696 who did not receive any sulfanilamide ninety-seven or 13.93 per cent, had a puerperal infection, and there was one death from peritonitis. Some interesting observations were made in a second series of women who had high temperatures before delivery as evidence of amniotic infection. Of five such patients treated before delivery with sulfanilamide three failed to show any signs of puerperal complications but the others presented symptoms of mild infection. Five other women who had high temperatures before delivery and who had not received any drug treatment all presented the clinical picture of severe puerperal infection, one dying of subacute peritonitis. Although it is too early to evaluate the benefits of the administration of sulfanilamide as a prophylactic measure against puerperal infection the results thus far have been encouraging and the treatment merits wider application.

#### Saenz Appointed Professor at Montevideo

The internationally known researches on the bacteriology of tuberculosis of Dr. A. Saenz of the Pasteur Institute of Paris have received recognition by the Medical School of Montevideo, Uruguay, which has just notified Dr. Saenz of his appointment as professor of bacteriology. He has been engaged in research work for the past ten years at the Pasteur Institute of Paris specializing in the bacteriology of tuberculosis. Dr. Saenz has been especially successful in isolating by the cultural method the tubercle bacillus from genito-urinary, cutaneous and meningeal localizations of this type of infection. His monograph on the bacteriologic diagnosis of tuberculosis has had a large circulation.

#### The Origin of Syphilis

Professor Aschoff, the Freiburg pathologist who is also interested in the history of medicine, has taken a stand with regard to the problem of whether syphilis was indigenous in Europe in ancient times. Scientists at one time believed that the disease had been imported into Europe by the sailors of Columbus. Then through the efforts of Sudhoff at Leipzig this theory came to be completely reversed, so that for many years the view has prevailed that syphilis has always been indigenous in Europe and that it merely chanced to appear in a particular severe form at the close of the fifteenth century. Sudhoff based his hypothesis in the main on data elicited from textual criticism. He claimed to have found in precolumbian European records a number of regulations issued in various cities allegedly to combat syphilis. Meanwhile it has been proved that the descriptions of symptoms with which Sudhoff bolstered his theory lacked uniformity and in all probability had to do with epileptic and epileptoid seizures. Consequently proofs of precolumbian European cases of syphilitic changes in the bones (and if possible, in the vascular system) were much needed in support of Sudhoff's theory. During the past ten or twenty years discovery of European paleolithic and neolithic sites containing human bones has been more and more frequent, yet in none of the skeletal remains was any trace of syphilitic change determinable. The old view of Virchow would thus seem to be substantiated. Sudhoff himself has pointed out that incontestable references to a venereal disease resembling syphilis are entirely lacking in the literary work of classical antiquity. About forty years ago at Marnet, France, ancient bones were discovered which at first were reported to exhibit syphilitic alterations. It was later proved that this observation was based on a geologic error.

Conversely, excavation of precolumbian burial sites in America has yielded skeletal material in which signs of syphilis are plainly evidenced. Yet such discoveries do not solve the problem of possible indigenous syphilis in Europe in ancient times. References to aneurysms are to be found in classical literature. Professor Aschoff, who made special mention of the American discoveries and these classical references, contributes greatly to the elucidation of the entire problem. Recently he was able to establish that the aneurysms described by the ancients were merely incised wounds of the smaller blood vessels of the extremities and of the head, produced by venesection. Conversely, the same authors even in medical case records make no reference whatever to the characteristic aneurysmal formation (usually at the arch of the aorta) of syphilitic origin. The more recent investigations made by Williams (1932) and the wholly new body of proof which he adduces with regard to syphilitic changes in precolumbian American skeletons are to Professor Aschoff far more convincing than Sudhoff's still dubious textual research. Professor Aschoff is therefore of the opinion that syphilis had no existence in Europe before the time of Columbus.

### Congress of the German Genetic Society

The German Genetic Society has in its membership interested biologists, botanists, zoologists and physicians. One useful feature of the society's discussions is the diversification of points of view based on the various scientific disciplines, with regard to problems of general interest. The recent congress discussed some questions of importance to human genetics.

On the first day F. Claussen of Frankfurt on the Main spoke on the pathology of heritable diseases. The parents of a tainted person may appear healthy and only by the most meticulous methods of examination will it be possible to elicit the slightest pathologic signs. In such cases one has to deal not with a recessive trait, as might be assumed on the basis of cursory examination, but with a dominant trait. Furthermore polypheny can also be present, that is to say, disorders having a more or less dissimilar clinical appearance may be genetically related. The divergent aspect of characters belonging to the same gene can be conditioned by diverse environmental stimuli. The stimuli may from time to time modify the action of the gene. Research on twins here offers a useful explanation. A pair of enzygotic twins present a much higher proportion of correspondence with respect to pathologic manifestations than do a pair of dizygotic twins. This circumstance bespeaks the largely hereditary conditionality of the trait in question. Genotypically related clinical syndromes come to be recognized through careful analysis and this makes possible a new classification of disorders, based on genetic points of view. It is possible to observe the most conspicuous symptom of a disorder without by any means understanding the gene action as a whole. Nevertheless, still other signs, less striking perhaps, may be coordinated with this particular gene, for example in deformities in which different groups are to be traced to the same gene, albeit with varying time of onset of the effect, as in disturbances in the growth of bone.

#### NORMAL CRANIOTICS

Prof. Eugen Fischer of Berlin-Dahlem discussed "normal genetics." The two factors that condition the development of the gene are heredity and environment. The action of the gene on the human vertebral column for example has been thoroughly investigated. Since it has been proved that analogous variations may occur in the vertebral column and the nerve plexus, the same gene would seem to be responsible for the distribution and structure of the vertebral column as well as for the distribution and structure of the great nerve plexus. Fischer next went into the problem of inverse symmetry and asymmetries. He contrasted the inherited asymmetries based on the action of a gene with those asymmetries which originate from slight environmental influences at work in utero. Other asymmetries, such as dextrality and sinistrality, can be understood not by a study of the individual but by a study of the population as a whole. They are explicable in terms of a purely environmental effect based on general developmental lability through various trivial circumstances such as position and curve of the embryo in quite early stages and the related divergent influence and nutrition of the two sides of the body. Finally there is the group of the true anomalies, known as deviating asymmetries. Irregularity of the cilia or freckles on the two sides of the body are typical anomalies of this group.

#### HERITABILITY OF PSYCHIC CHARACTERS

Gottschaldt of Berlin-Dahlem lectured on "phenogenesis in psychology." His point of departure was the premise that the heritability of psychic characters has been proved through research on twins and that normal characters are as a rule polymERICALLY conditioned. In camps for twins which have been organized for the express purpose of conducting these tests it has been possible to demonstrate the hereditary conditionality of certain traits. The prevalent mood shows a

proportionately greater correspondence in enzygotic twins. A preponderant hereditary conditionality is also evidenced by other psychic qualities, such as responsivity, impulsiveness, intellectual capacity and the intelligence. For pathologic mental activity, various types of hereditary transmission should be assumed. The author believes that, just as there are racial differences in the physique, there are likely to be differences in the realm of the psyche.

### Law to Regulate Orthopedic Shoes

Regulation of the manufacture of orthopedic footwear has been decreed by the interested ministers. Hereafter orthopedic shoes can be made only by cobblers who have undergone special training and received a special certificate. An orthopedic shoe is a custom made product of handicraft which differs from the so called normal shoe in the manner of its manufacture and in the general contour or in structural details. The individual peculiarities of orthopedic footwear are determined by pathologic anomalies in the soft parts or in the bones of the foot or leg of the destined wearer, form and function alike may be taken into consideration. In order to prepare for the special examination the cobbler must undergo at least six months of training in a special recognized school or, in lieu of this training, offer one year's experience as assistant to an orthopedic master cobbler. The new law should certainly represent an improvement, orthopedic footwear should henceforward be orthopedic in fact as well as in name.

## Marriages

BEN NALAN MILLER JR., Columbia, S. C., to Miss Ruth Elizabeth Gambill of West Jefferson, N. C., in North Wilkesboro, N. C., in December 1938.

HERMAN LLOYD SCHIFFS, Shelley, Idaho, to Miss Betty Lee Miller of New Sweden at Logan, Utah, Sept. 25, 1938.

DANIEL NIVEN STEWART JR., Hickory, N. C., to Miss Nan Norman of Gastonia, in Norfolk, Va., Dec. 22, 1938.

HORACE GILBERT STRICKLAND to Miss Agnes McIntyre Leak, both of Greensboro, N. C. in December 1938.

MAURICE VERNON SHIELDS to Miss Phoebe Ann Sheldon, both of Newcomerstown, Ohio, Oct. 31, 1938.

SIMON ANDREW SCHLUETER to Miss Mary Catherine McGarry, both of Akron, Ohio, recently.

INA MORRIS HARPER to Mr. F. Le Roy Bradford, both of Benton Harbor, Mich., Dec. 31, 1938.

CHARLES A. HOFFMAN to Miss Margaret Lynn Jack, both of Huntington, W. Va., Dec. 21, 1938.

VINCE MOSELEY to Miss Matilda Elizabeth Holleman, both of Durham, N. C., Oct. 11, 1938.

JAMES MILO SHAFFER, Cincinnati, to Miss Mary Louise Ailes of Anna, Ohio, Nov. 23, 1938.

MARK P. HOLLAND, Mahanoy City, Pa., to Miss Edith Ditchey of Timbiqua, Nov. 24, 1938.

JAMES B. SEELEY, Dearborn, Mich., to Mrs. Corette Cowan of Detroit in October 1938.

JOHN R. SHOENMAKER to Miss Bette Hunter, both of Cuyahoga Falls, Ohio, Nov. 16, 1938.

LYNN E. SHARRAI, Lincoln, Neb., to Miss Mary Ellen Ahern of Shubert., Oct. 17, 1938.

FREDRICK W. SIEGERT, Pana, Ill., to Miss Anne Arpe of St. Louis, Oct. 27, 1938.

JOHN SPROULL to Miss Daurice V. Haley, both of Haverhill, Mass., in October 1938.

IRVING WEINSTEIN to Miss Blanche Sukoemg, both of New York, Aug. 21, 1938.

JOHN B. SUINO to Miss Virginia O. Byrne, both of La Salle, Ill., in October 1938.

EDSON J. ANDREWS to Miss Lola French, both of Milwaukee, Nov. 24, 1938.

## Deaths

**Anton Schwartz Schneider**, Plattsburg, N Y, Albany (N Y) Medical College 1920, member of the Medical Society of the State of New York and the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, on the attending staff of the Physicians Hospital and Children's Home of Northern New York, Plattsburg, and the Clinton Prison, General and Tuberculosis Hospital, Dannemora, aged 48, died, Nov 19, 1938, of coronary thrombosis

**Alexander Macalister**, Camden N J, University of Pennsylvania Department of Medicine, Philadelphia 1885 member of the Medical Society of the State of New Jersey, past president of the Camden County Medical Society formerly secretary of the State Board of Medical Examiners of New Jersey, past president of the Camden County Tuberculosis Association, aged 76, died Nov 22, 1938 of carcinoma of the stomach with metastasis

**William W Bachman**, Bath, N Y University of Buffalo School of Medicine, 1899, member of the Medical Society of the State of New York, at one time health officer of the town and village of Prattsburg, superintendent of the Pleasant Valley Sanatorium on the consulting staff of the Veterans Administration Facility, on the staff of the Bath Memorial Hospital, aged 64, died Nov 28, 1938, of hypertensive heart disease

**Carl Jacob Leutenegger**, Buffalo, University of Buffalo School of Medicine, 1920 associate in urology at his alma mater, member of the American Urological Association on the staffs of the State Institute for the Study of Malignant Diseases Buffalo General Hospital, City Hospital, Our Lady of Victory Hospital and the Children's Hospital, aged 45, died, Nov 24, 1938, of aplastic anemia and tuberculosis

**Frank Thomas Duffy**, Los Angeles, Bennett College of Eclectic Medicine and Surgery, Chicago, 1914 member of the Illinois State Medical Society, served during the World War, was commissioned in the U S Veterans' Administration and held various high positions, aged 48, died, Nov 17, 1938 in the Veterans' Administration Facility of coronary thrombosis

**Vito Luigi Raia**, Providence, R I, Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy 1883, on the consulting staff of the Rhode Island Hospital fellow of the American College of Surgeons, aged 81, died, Nov 21, 1938 in the Jane Brown Memorial Hospital of carcinoma of the colon, intestinal obstruction and pneumonia

**Clarence Henry Hall**, Cherokee, Iowa Medico-Chirurgical College of Philadelphia, 1904, past president of the Cherokee County Medical Society, veteran of the Spanish-American War formerly on the staff of the Sioux Valley Hospital aged 61, died suddenly, Nov 30, 1938 of coronary sclerosis and diabetes mellitus

**Mark Gorman Gates**, Santa Monica, Calif Los Angeles Medical Department of the University of California, 1910, on the courtesy staff of the Santa Monica Hospital aged 52 was drowned Nov 15 1938, near Kernville, when he fell into an irrigation canal while on a hunting trip

**Walter Parks Bliss**, Pasadena Calif, Columbia University College of Physicians and Surgeons New York, 1916 on the staff of the Collis P and Howard Huntington Memorial Hospital, aged 49 was found dead Nov 3 1938 of a self inflicted knife wound of the heart

**Alva P Maine**, Webster N Y University of Pennsylvania Department of Medicine Philadelphia 1870 for many years health officer and member of the school board past president of the village aged 92 died, Nov 7, 1938, of diabetes mellitus and myocarditis

**Edgar Franklin Magenheimer**, Evansville, Ind, Indiana University School of Medicine Indianapolis 1910, served during the World War on the staffs of the Deaconess Hospital and St Mary's Hospital, aged 51 died Nov 27, 1938 of cerebral hemorrhage

**William Henry Redmond**, Cedar Rapids Iowa Northwestern University Medical School Chicago 1910 past president and secretary of the Linn County Medical Society, served during the World War, aged 53 died Nov 5 1938 of coronary thrombosis

**William Wilson Gingles**, Castana Iowa, Kentucky School of Medicine Louisville 1890, member of the Iowa State Medical Society formerly secretary of the Monona County Medical Society, aged 71, died Nov 10, 1938, of acute dilatation of the heart

**James Francis Power**, New York, Bellevue Hospital Medical College, New York, 1898 consulting otolaryngologist to St Johns Long Island City Hospital, Long Island City, N Y, aged 64, died, Nov 25, 1938 of cerebral embolism

**Alphons E Bachhuber**, Mayville, Wis, Northwestern University Medical School, Chicago, 1898, past president and secretary of the Dodge County Medical Society, aged 61, died, Nov 24, 1938, of coronary thrombosis

**David Arch Rannels**, Chillicothe, Ohio, Starling Medical College, Columbus, 1891, veteran of the Spanish-American War, aged 72 died, Nov 11, 1938, in the Veterans Administration Facility of bronchopneumonia

**Carl Wurm**, Pleasantville N Y, Bellevue Hospital Medical College, New York 1892, member of the Medical Society of the State of New York aged 75, died, Nov 1, 1938 of carcinoma of the stomach and liver

**Eugene Thomas McNamara**, Somerville, Mass Tufts College Medical School, Boston, 1896, Bellevue Hospital Medical College, New York 1897, aged 79, died, Nov 19, 1938, in Melrose of chronic nephritis

**William Jacob Bott**, Rockville Centre, N Y, University of Buffalo School of Medicine, 1898, served during the World War aged 65, died, Nov 22, 1938, of coronary thrombosis and arteriosclerosis

**Hugh Howard Mitchell**, Regina Sask, Canada, University of Toronto Faculty of Medicine 1910, for many years coroner, superintendent of the Regina General Hospital, aged 55, died, Oct 14, 1938

**Arthur Alexandre La Rue**, Worcester, Mass, Baltimore Medical College, 1901, formerly member of the board of health of Waltham, Mass aged 61, died, Nov 1, 1938, of chronic myocarditis

**John C Moore**, Trenton Tenn, University of Louisville (Ky) Medical Department 1875, Jefferson Medical College of Philadelphia, 1881, aged 86 died, Nov 25, 1938, of pneumonia

**John Huntington Lewis**, Cincinnati, Cincinnati College of Medicine and Surgery, 1896, aged 68, died Nov 7, 1938 in St Mary Hospital of cardiorenal disease and arteriosclerosis

**Lorne Joseph Violette**, St Leonard, N B, Canada, University of Montreal Faculty of Medicine, 1911, for several years mayor, aged 54, died, Oct 6, 1938

**Declan Edward Foley**, Los Angeles, Queen's University Faculty of Medicine, Kingston, Ont, Canada, 1886, also a priest, aged 75, died in October

**Edward Allmeroth**, St Louis, St Louis College of Physicians and Surgeons, 1891, aged 69, was found dead, Oct 16, 1938 of chronic endocarditis

**Ulysses M Carwell**, Hendricks W Va University of Virginia Department of Medicine, Charlottesville, 1898, aged 65, died Oct 17, 1938

**August Pohlman**, Philadelphia, Baltimore Medical College, 1896, also a clergyman, formerly a medical missionary aged 74, died Oct 9, 1938

**Alonzo Garrett**, Gallipolis, Ohio (licensed in West Virginia in 1888), Civil War veteran, aged 91, died, Nov 1, 1938, of coronary occlusion

**John Jackson Rivenbark**, Samson, Ala, Georgia College of Eclectic Medicine and Surgery, Atlanta, 1897, aged 77, died, Oct 17, 1938

**John Archibald MacMurchy**, Dresden Ont, Canada, University of Toronto Faculty of Medicine, 1916, aged 53, died, Nov 28 1938

**Angus A McLean**, London Ont Canada, University of Toronto Faculty of Medicine Toronto 1907, aged 58, died, Nov 9, 1938

**Milton Newman**, New York University of Southern California School of Medicine, Los Angeles, 1935, aged 29, died, Oct 1 1938

**William Angelo Mott**, Rathwell Man, Canada Manitoba Medical College, Winnipeg 1907 aged 73, died, Oct 20 1938

**Gustav A Christensen**, Cass Lake Minn (licensed in Minnesota under the Act of 1887) aged 74, died Oct 9 1938

**Wilson Yates Young**, Toronto Ont Canada Trinity Medical College Toronto 1895 aged 73 died, Oct 7 1938

**Oliver S Burns**, Lebanon, Va Kentucky School of Medicine Louisville, 1885, aged 73, died Oct 26 1938

**Walstein M Tompkins**, New York University of Buffalo School of Medicine 1898, aged 79, died, Oct 13, 1938

**Thomas Jones Mendenhall**, Rosston Ark (licensed in Arkansas in 1903) aged 73 died Oct 6 1938

isolate the virus from the nasopharynx (Trask and Paul and others) and from rectal washings (Harmon, Krigsten and Harkins) within the first ten days after the onset of paralysis. However, there are a few isolations of the virus on record, made more than a month after the onset of the disease and from persons (healthy carriers) who have never had the disease. To add to the present confusion, the time honored concept of this disease as being spread by nasopharyngeal secretions has been questioned as the result of finding the virus in the intestinal tract of man convalescent from the disease (Harmon, Krigsten and Harkins, confirmed by Kramer) and by the failure to find lesions in the olfactory bulbs in fatal cases in man (Sabin).

At the present time it appears that a rigidly enforced quarantine of three weeks after the onset of the disease is adequate. The effectiveness of closing schools and preventing the congregation of children in attempting to control epidemics has been questioned.

EFFECT OF SHOCK ON DRUNKENNESS

To the Editor—Could shock such as that sustained following an automobile accident with a resulting head injury and temporary loss of consciousness, cause a man who had been drunk before the accident to become sober? In this particular case there are five witnesses who will swear that the person involved was drunk before an accident and when I saw him a few minutes afterward he was definitely sober. It is my opinion that if this man had a high enough concentration of alcohol in his blood stream to cause drunkenness shock would not eliminate it fast enough to sober him up immediately. Am I correct in this?

M D New York

ANSWER—It is not unusual for a drunken man to appear to be sober after an accident. This sobering effect has nothing to do with elimination of alcohol but is largely a psychic phenomenon, probably associated with a temporary redistribution of alcohol in the body. Just as a sleepy or apparently exhausted person can pull himself together when the occasion demands, so the drunken person may be able to control himself as long as an unusual mental or physical stimulus has sufficient effect. He is simply compensating for the toxic action of alcohol by increased effort. When the stimulus has been removed he usually reverts to a state of drunkenness. This fact is extremely important, since many persons escape conviction as drunken drivers because they are able to give a good account of themselves when in contact with the police, and it is only through chemical tests for alcohol in body fluids that the correct diagnosis can be made.

Elbel in Die wissenschaftlichen Grundlagen der Beurteilung von Blutalkoholfunden, page 93, explains the sobering effect of emotional stimuli by consideration of the action of epinephrine on the body. If the adrenal glands are extirpated in an animal, the tolerance for alcohol is greatly decreased. Also ordinary amounts of alcohol cause splanchnic vasoconstriction and a correspondingly increased intracranial circulation of alcohol containing blood. When fright or excitement occurs, the sudden splanchnic vasodilatation is associated with a decreased circulation of alcohol through the brain.

AGE DISTRIBUTION OF DIPHTHERIA AND FREQUENCY OF RECURRENCES

To the Editor—1. What percentage of cases of diphtheria occur between ages 14 and 20? 2. What percentage of cases in adults? 3. What is the frequency of recurrences in an individual having had a proved case?

M D Texas

ANSWER—Age incidence for diphtheria is influenced by special factors in different communities. For example, after an immunization campaign among children of preschool age the percentage of diphtheria patients in the higher age groups will be more evident. If the immunization campaign is carried out energetically among school children as well as those of preschool age, the percentage of adults with diphtheria in a large city is likely to be noticeable.

1. Ordinarily the proportion of cases between 14 and 20 is about 8 per cent.

2. The proportion of cases in adults (those 16 years and over) is about 10 per cent. Nevertheless in a large contagious disease hospital during the years 1935 to 1937 inclusive among 1,298 diphtheria patients treated 18 per cent were adults, that is 16 or more years of age.

3. Second attacks of diphtheria are not exceedingly uncommon. However among 20,000 hospital cases of diphtheria the rate was approximately 0.1 per cent.

According to the annual report of the chief medical officer of the Ministry of Health (Great Britain) for the year 1937, approximately 90 per cent of all cases of diphtheria occur under 15 years of age.

POSSIBLE PAROXYSMAL HYPERTENSION

To the Editor—A white man aged 56 weighing 240 pounds (109 Kg) complains of a chilly sensation up and down his spinal column occurring when sitting at his desk driving his automobile walking or in a theater. This sensation is followed in a few minutes by a complete blanching of his entire body usually beginning on the hands, which lose their normal pink color and become extremely pale and white. His face becomes white and following this goose pimples appear over his body. He says that at this time his arm from his elbow feels numb and lifeless. Immediately after this he becomes weak and his legs want to buckle under him he says. Within three to ten minutes his normal color will return. He feels fairly well except for being extremely weak. He sometimes suffers eight or ten attacks during a day. At times the blanching appears only on one arm and hand the other arm and hand remaining pink in a few minutes they resume the normal color. His blood pressure has varied from 90/76 to 150/76. His pressure has varied as much as 40 points in each arm. All laboratory work gives normal results. The electrocardiogram is normal. X-ray studies of the chest are negative. I should like to know the cause and treatment of this phenomenon.

M D, Ohio

ANSWER—The situation described is an unusual one. It is apparent that the patient suffers from extreme stimulation of the sympathetic nervous system during the episodes described, since they are characterized by vasoconstriction (blanching of the skin) and "goose pimples." It is important to know the values of the blood pressure and the pulse rate during one of these episodes. The condition is suggestive of paroxysmal hypertension due to adrenal tumor. If there is definite elevation of the blood pressure and tachycardia during the episodes described, this possibility should be distinctly considered. A tumor of the adrenal gland which causes paroxysmal hypertension may be palpated occasionally and sometimes causes sufficient displacement of the kidney to show changes in the excretory urograms. In some instances it is advisable to inject air around the kidney in an attempt to visualize such tumors. The correspondent is referred to the following articles on paroxysmal hypertension.

Pincoffs M C Paroxysmal Hypertension Associated with Suprarenal Tumor *abstr THE JOURNAL* July 6 1929 p 63  
Mayo, Charles H Paroxysmal Hypertension with Tumor of Retroperitoneal Nerve *THE JOURNAL* Sept 24 1927 p 1047

QUININE FOR INFLUENZA

To the Editor—The head of our nursing school brought me a pamphlet edited by the Cinchona Products Institute Incorporated New York in which the value of quinine as a preventive agent in influenza is extolled. The bibliography which includes some thirty six authors contains only one article published in this country (Frankel *New York M J* Nov 23 1938). I told her that I had no opinion on the subject. May I ask whether or not there is evidence that the drug has prophylactic value during epidemics of influenza?

H D PALMER M D Rockford Ill

ANSWER—While much material has developed regarding the value of quinine as a preventive and a therapeutic agent in influenza, the evidence at hand does not support the claims. Certain reports have stressed the fact that large doses of quinine must be used before the onset of infection and that under these conditions fewer individuals come down with the disease while others have thought that the administration of the drug in such a manner afforded benefit only by lessening the severity of the disease. There has been equally good or even better evidence that in the north temperate climate this effect of quinine has not been so striking. The same effects have been reported for antipyrene and the results, if any, are in the latter instance better than they are for quinine. To date it is safe to say that no one drug has established itself as an efficient prophylactic.

APPENDICAL ABSCESS

To the Editor—Please give references or definite technical information on opening an appendical abscess extraperitoneally.

RAYMOND H McPHERSON M D Chicago

ANSWER—Roger Vaughan, writing on appendicitis in Nelson's Loose-Leaf Surgery (vol V, page 341 L), objects to the extraperitoneal route of abscess evacuation on account of the inability of the surgeon to explore for secondary abscess and because intraperitoneal damage may occur without the operator's knowledge of the accident. On the other hand, Sir James Berry in his oration before the Medical Society of London in 1932 (Fallen Idols. The Case of Appendicitis, *Lancet* 1 1027 [May 14] 1932), tracing the entire history of appendical surgery, states that the experience of half a century has taught that local drainage preferably extraperitoneally, is the method of choice in all walled-off appendical abscesses. He further cites the case of King Edward VII, whose life was undoubtedly saved by a small incision and drainage of an appendical abscess. Orr, in the

discussion of treatment of appendical abscess (*J Missouri M A* 31 232 [June] 1934), states that "if, instead of subsiding, the [appendical] mass increases in size and develops into a well defined abscess, drainage is indicated. The abscess should be drained extraperitoneally through a small incision when possible. A small percentage may be drained through the vagina or the rectum. If the peritoneal cavity is opened when the incision is made, it is safer to pack gauze down to the abscess wall, making a sealed channel to the surface of the body, through which the abscess may be drained later. No effort should be made to remove the appendix when a localized appendiceal abscess is drained." In a surgical clinic J N Coombs (*S Clin North America* 14 173 [Feb.] 1934) shows by an excellent illustration the retroperitoneal approach to an appendiceal abscess. Most surgeons agree that the mortality in the neglected case of appendicitis has been distinctly lowered by conservative surgery, consisting in waiting until there is definite abscess formation and drainage through a small opening, carefully avoiding the free peritoneal cavity.

#### HIGH PALATAL ARCH IN YOUNG WOMAN

To the Editor—A woman aged 20 has an exceedingly high palatal arch which greatly obstructs her nasal passages. At the age of 6 her tonsils and adenoids were removed, nevertheless she has been a mouth breather and has a high arch. Would you advise either removal of the lower turbinates or removal of one or more molar teeth or both?

C B GREAR MD Honaker Va

ANSWER—Malformations of the face and jaws are dependent on local and systemic factors, prenatal and postnatal in their influence. Of the local factors, mouth breathing due to nasal obstruction from any cause is usually cited as causing narrow high arched palates and narrow nasal cavities with subsequent malocclusion. It is true that some such cases are probably caused by the lack of nasal ventilation, for they may be watched in their development after nasal obstruction. On the other hand, the so-called adenoid facies may be seen in children without adenoids, and tracheotomy tubes have been worn by children for years without any ill results on the nasal or palatal development. Thus it is probable that nasal obstruction and high palatal arch do not necessarily have a cause and effect relationship.

In the patient under discussion it is likely that, with the malformation well established and present at the age of 20, corrective procedures would be ineffective in correcting the condition. It may be that some intranasal surgical procedure, trimming the lower portions but not entirely removing the lower turbinates, may give enough increase in nasal space to constitute mechanical relief and allow nasal respiration. However, this would not change the palatal configuration, which is probably permanent.

#### OXYGEN REQUIREMENTS AT HIGH ALTITUDES

To the Editor—I am interested in obtaining information concerning the use of oxygen for human beings at high altitudes or in the stratosphere. I have so far been unable to find any references on the quantity of oxygen needed for respiration. If there has been any research as to vital capacity and total oxygen used in high altitude such as mountain tops compared to sea level I should like to know about it. What other reaction does one have to consider besides oxygen consumption in sending a patient by air? I would appreciate any reference that would give quantitative amounts of oxygen used and foot pounds of energy necessary for the extra work of the heart in high altitude. M D California

ANSWER—Experiments in the low pressure chamber, as well as investigations in which various oxygen concentrations were inhaled at normal barometric pressure, indicate that the oxygen consumption is unchanged when the oxygen concentration is diminished to 13 per cent. At lower concentrations of oxygen such as from 8 to 10 per cent, the oxygen consumption is diminished.

Experiments carried out by Zuntz and von Schrotter showed an insignificant rise in the oxygen consumption in a balloon flight up to an altitude of more than 5,000 meters. Observations carried out at high altitudes did not reveal any change in oxygen consumption at an altitude below 3,000 meters. Increases in oxygen consumption were observed at altitudes varying from 3,600 to 4,500 meters but the great variability of the results obtained suggests that differences in temperature and nonbasal conditions are largely responsible for the increases in metabolism observed.

According to Grollman (*Am J Physiol* 94 287 [Aug.] 1930) the minute volume increased by 40 per cent on Pike's Peak. Similar results were obtained by Ewig and Hinsberg (*Ztschr f klin Med* 115 732 1931) in Switzerland.

It must be taken into consideration that these increases in minute volume are only temporary and that normal values may be obtained again after the number of blood corpuscles have increased sufficiently.

#### CONNECTIONS BETWEEN THALAMIC AND HYPOTHALAMIC NUCLEI

To the Editor—Please discuss the connection between the various nuclei of the thalamus to the hypothalamus and periventricular nuclei. I should like to know whether there is such a connection established in man.

JOHN GARB, MD, New York

ANSWER—Relatively little is known concerning the connections between thalamic and hypothalamic nuclei. The mammillo-thalamic tract, which arises from the medial mammillary nucleus and ends in the anterior nuclei of the thalamus, is said to contain some fibers running in the reverse direction. Periventricular fibers, running close to the wall of the third ventricle, join the thalamic nuclei of the midline with the hypothalamic nuclei and more especially with the posterior hypothalamic nucleus. These connections probably contain both ascending and descending fibers. It is probable that the dorsomedial nucleus of the thalamus may receive impulses from the hypothalamic and periventricular nuclei and relay them to the frontal cerebral cortex. What little is known concerning these connections is based on the study of mammalian brains and can only tentatively be applied to man. The chief papers dealing with this subject are those of

Clark W E Le Gros Functional Localization in the Thalamus and Hypothalamus *J Ment Sc* 82 99 (March) 1936

#### ABNORMAL BREAST AND CHILDBIRTH

To the Editor—As a child a primipara who is now about four months pregnant suffered a severe burn of the right side of the chest. There is a good deal of scar formation and no nipple present on the right side. The breast itself is fairly well developed. What procedure should one follow when the breast becomes greatly distended in later months and after delivery? Is a tight dressing all that is necessary? Would it be best to dry up both breasts as soon as possible? M D Ohio

ANSWER—Although there may be considerable congestion of the breasts following delivery, it may be possible to continue nursing from the breast which has the normal nipple. The abnormal breast will undergo considerable congestion, but in several days this should decrease and eventually subside completely. During the interval, ice caps and a tight binder can be applied to the breast which is to be dried up. The aim in a breast will secrete only as long as there is an exit for the milk. When the milk secretion fails to be removed, these glands undergo atrophy. During the latter part of pregnancy, a breast support will give relief if there is any discomfort.

#### NO BLOOD TEST FOR RACE DIFFERENTIATION

To the Editor—Several of us are anxious to know whether any work has been done to differentiate by the precipitin test the blood of Negroes from the blood of white persons. We have read one or two of the conventional toxicologies and no mention was made of this.

M D Alabama

ANSWER—Since the introduction of the precipitin test attempts have been made to apply this technic for the differentiation of human bloods of different races, particularly bloods of Negroes and white persons. For the latest attempt to develop such a test see the paper by Fischer and Racquet (*Ztschr f Immunitätsforsch* 94 104, 1938). Though from time to time reports have appeared in which the writers claim to have succeeded in differentiating blood of various races, none of these claims could be confirmed by subsequent investigation. All authorities agree at the present time that it is not possible to differentiate the bloods of Negroes and white persons by the precipitin test.

On the other hand there are certain serologic differences between Negro and white blood of a statistical nature. For example, group B is more frequent in Negroes in New York City than in white persons, and in addition subgroup A<sub>2</sub> occurs more often in Negroes, and also the so-called agglutinin P (Landsteiner Karl and Levine Philip *J Immunol* 18 87 [Feb.] 1930). Several years ago Landsteiner, Strutton and Chase (*ibid* 27 469 [Nov.] 1934) discovered a rare agglutinable property in human blood with the aid of agglutinating serums obtained by immunizing rabbits with the blood of a particular Negro. This rare agglutinin was far more common among Negroes than among white persons.

## Book Notices

**The Pneumonias** By Hobart A Reimann M D Professor of Medicine Jefferson Medical College Philadelphia. With a foreword by Rufus Cole. Cloth Price \$5.00 Pp 381 with 111 illustrations Philadelphia & London W B Saunders Company 1938

Thus is the second recent presentation which classifies etiologically acute inflammations of the lungs or pneumonias and presents them as individual diseases. The pathologic histology of the various pneumonias is expounded most acceptably and beautifully illustrated. To avoid any anatomic implications, Dr Reimann discusses the pneumonias in part I A, on pneumococcal lobar pneumonia, and I B, on atypical pneumonia, giving as synonyms bronchopneumonia, lobular and catarrhal and diffuse pneumonia and pneumonitis. Part II is devoted to pneumonia as a specific form occurring as part of a systemic disease. Part III discusses pneumonias secondary to acute and chronic disease, mechanical shock, senility and so on caused by mixed infection. Strict adherence to the author's classification leads to some reduplication, such as presentation of influenzal pneumonia and tuberculous pneumonia in two separated sections and also to such a cryptic statement as one on page 325 "In the usual form in nonspecific atypical pneumonia, the earliest typical roentgenographic evidence is the appearance of small moderately dense irregular shadows".

Because of its succinct presentation of much valuable material, this volume should be accessible to all who study and treat acute respiratory diseases. In a scientific presentation in book form such statements as "from the literature" or "from various authors" attached to charts are inappropriately incomplete because they cannot be verified or critically evaluated. The statement that "in normal persons the upper air passages generally harbor a variety of potentially pathogenic micro organisms" is debatable and is an example of statements which lack adequate bibliographic or other documentation. In some instances emphasis is ill placed. More space is given to the rare experimental vaccinal pneumonia than to the entire discussion of oxygen therapy. The latter is limited to three fourths of a page and omits both descriptive details of treatment and the basis for the selection of apparatus.

So that they may be corrected in a future edition, some misstatements and omissions are called to the attention of the author. On page 27 the description of the effect of injecting carbohydrate during pneumonia and in the response to serum therapy is

reversed. On recovery from pneumonia and when ample serum is given, the skin reaction (described by Francis) appears (not disappears as stated). On page 75 only vitamin A is mentioned in the section on metabolism. Vitamins B and C are not mentioned, although vitamin C has been studied in its relation to pneumonia. On page 142 there is no adequate evidence for the retention of chlorides during pneumonia. The studies of Peabody and of Greenwald refute this old belief. On page 157 the advice that serum should be stopped if several severe reactions occur would be better if changed to read that a different lot or kind of serum should be used. On page 140, such a statement as "experience in large hospitals, however, shows that it is quite safe for a patient to be placed unscreened in a general ward, at least as far as the danger of contagion among immediately neighboring patients is concerned, since cross infection seldom occurs" is harmful because false, unless modified to state that wide spacing of beds is provided and an aseptic technic practiced. Where the matter has been studied, ample evidence has been provided to show that cross infections occur, even among pneumonia patients. The practice in Scotland and in some large American hospitals of removing pneumonia patients from general medical wards is justified.

**Le duodénum. Atlas de radiologie clinique.** Par P. Cottenot, médecin radiologiste de l'Hôpital Broussais, Max Lévy et Ed. Chériglé, assistant de radiologie de l'Hôpital Broussais. Préface de M. Robineau. Cloth. Price 235 francs. Pp. 223 with 394 illustrations. Paris: G. Doin & Cie, 1938.

This highly practical work, presented in atlas form, essays to provide a sound basis for the training of physicians who wish to undertake the interpretation of roentgenographic and screen appearances in the upper digestive tube and to supply a font of experience in the form of a rich collection of interesting and proved duodenal cases with which to make comparisons. The opening pages are concerned with technical considerations, followed by a discussion of the numerous variations from the usual normal that may be encountered, then in turn are passed in review the various chapters of duodenal abnormalities with a concluding chapter on the radiologic aspects of the stomach and upper small bowel after duodenal operations. The illustrations are abundant, well chosen and excellently reproduced, with clarifying schematic drawings provided for each. Only cases are included which have been well worked up and the diagnosis verified indisputably. This is a valuable contribution to the radiologic and gastro-enterologic specialties.

**Slums of New York.** By Harry Manuel Shulman. Cloth. Price \$3. Pp. 394. New York: Albert & Charles Boni Inc., 1938.

The reader picking up this book from a sense of duty, anticipating a dull and depressing catalogue of human misery and degradation or a social worker's crusade is soon agreeably surprised to find a readable and interesting character study of slum neighborhoods and tenement demizens. The book deals with four typical slum areas, which are briefly described as follows: Tyler Street is an Old World community, Fleet Street a cross-roads between Occident and Orient, Parnell Street an old slum and Palm Street a "conflict of cultures." The first section of the book is descriptive of the slum areas to be studied, from a general point of view. Then follow chapters more specific in character, dealing in each instance with the slum in its relation to the family and then, in a separate chapter with the social world of the child in each of these areas. Each general chapter on each of the areas under study deals with composition of the population, housing, broken and disorganized homes, family accord and discord, health of parents, effects of the depression adjustment to slum life, language and literacy, social institutions and family life, adult antisocial behavior, and social selection as a factor in the crime rate. Typical chapters on the social world of the child treat of education, retardation, attitudes toward schools, health, employment, the home, outdoor play, clubs and organizations, summer recreation, supervised recreation, commercial recreation, parental supervision, behavior disorders and juvenile delinquency. Throughout the approach appears objective and free from preconceived theories which it is sought to prove.

Most interesting to the medical reader is the treatment of the health situations in these slums. Except for one suggestion among the conclusions to the effect that the school must look

after the health of the children unless some other agency does so, one finds here no suggestion of the stock in trade of the advocates of medical socialism, no suggestion that all the evils of poverty can be remedied by merely providing more and cheaper medical care. The author has not apparently been misled into confusing causes and effects and prescribing the superficial remedy of more medical care for the deep-seated economic, social and cultural causes which underlie the manifestation known as a slum. Instead, he challenges public education to furnish the cultural stimuli which will penetrate the barriers of lethargy, lingual obstacles and adherence to Old World traditions and furnish the dwellers in these slum areas with cultural interests and with educational opportunities to prepare them for a more fully rounded life.

**Klinische Infektionslehre. Einführung in die Pathogenese der Infektionskrankheiten.** Von Dr. med. habil. Felix O. Höring, Oberarzt der II. Medizinischen Klinik und Dozent an der Universität München. Mit einem Geleitwort von Professor Dr. A. Schlittenhelm. Paper. Price 9.60 marks. Pp. 184. Berlin: Julius Springer, 1938.

This presents an interesting and instructive discussion of the genesis of infectious diseases from the point of view of the symbiotic relations between the host—the patient—and the specific infectious agent. The common principles of the various manifestations as distinct diseases of this symbiosis under different conditions are clearly set forth. Reading the book will serve to clarify and enlarge the understanding of the infectious diseases because so to speak, it bridges the gaps between microbiology, immunology and these diseases as usually presented in the medical curriculum.

**A Manual of Reporative Plastic Surgery.** By J. Eastman Sheehan, M.D., F.A.C.S., Professor of Plastic Reporative Surgery, New York Polyclinic Medical School and Hospital, New York. Cloth. Price \$5.50. Pp. 311 with 332 illustrations including 18 plates. New York & London: Paul B. Hoeber Inc., 1938.

**Plastic Surgery.** By Arthur Joseph Barsky, M.D., D.D.S., Associate Surgeon in charge of the Department of Reconstructive Surgery, Beth Israel Hospital, New York City. Cloth. Price \$5.75. Pp. 355 with 432 illustrations. Philadelphia & London: W. B. Saunders Company, 1938.

**Plastische Anatomie. Die konstruktive Form des menschlichen Körpers.** Von S. Möllner. Second edition. Cloth. Price 36 marks. Pp. 280 with 468 illustrations by Hermann Sachs. Munich: J. F. Bergmann, 1938.

Three books on the plastic art within a short period certainly indicate a growing interest in this recently revived but ancient specialty. At present many interesting books are available. The recent additions by Sheehan and his former associate Barsky will no doubt be welcomed by those who found the previous publications in this country too restricted in scope. Both of these authors have attempted to extend their text beyond the province of one specialty and have taken the broader view of plastic surgery in its fundamentals as applicable to all fields of surgery.

Sheehan, whose previous books on plastic surgery of the orbit and plastic surgery of the nose won him such renown, now turns his attention to the subject of autoplasmic repair and devotes a third of his new book to a discussion of the principles of tissue restoration. His long experience in the field has ably fitted him for the task and one finds it easy to read and understand these basic facts which he has boiled down to a comparatively few pages. The remainder of the book is taken up with the application of these principles to certain common conditions in the field of eye, ear, nose and throat, the oral cavity, the hand and cutaneous conditions.

Barsky's book follows a similar pattern but devotes less space to the fundamentals and more to the actual technic in various locations. One is amazed at the wide field that is covered in this comparatively small book. The author states that it was his intention to show only those operations which are typical for certain conditions, thus implying that many other procedures are available. It is therefore a book which should appeal to those who are preparing themselves for this type of work as well as to those who are doing only a modest amount of it. General surgeons will find much that is helpful in both books and every surgeon who expects to treat traumatic cases necessitating reparative procedures should acquaint himself with the many fine details which make for more successful results and which have been brought down to date by both of these authors.

Möllner's book is intended primarily for artists and sculptors and is concerned with the study of the framework of the body.

as manifested by and having an influence over its contour. The bones, muscles, ligaments and joints are discussed from the point of view not only of supporting structures but of plastic materials subject to certain limitations of motion and flexibility. Much of the value of the book lies in the beautiful colored drawings by Hermann Sachs, which seem to breathe life into an otherwise rather dry subject. Orthopedists might find this book valuable in their daily practice because of the attention given to the mechanics of the joints, muscles and ligaments and their influence on posture and motion.

**Lehrbuch der speziellen pathologischen Anatomie für Studierende und Ärzte** Von Dr. Eduard Kaufmann. Band II. Teil 1. Lieferung 1. Knochen, Gelenke, Muskeln, Sehnen, Sehnenscheiden, Schleimbeutel. Anhang: Literaturangaben. Bearbeitet von Georg B. Cruber. Ninth and tenth edition. Paper. Price 30 marks. Pp. 993, 1367, 207\*, 279\* with 247 illustrations. Berlin: Walter de Gruyter & Co. 1938.

This is the first instalment of the first part of the second volume of the ninth and tenth edition, revised and enlarged of Kaufmann's well known Pathologic Anatomy. The first volume, 991 pages, was published in 1931 and the second part of the second volume, which consists of the references (206 pages) for volume I, was published in 1932. The remaining instalments of the book will appear shortly. According to the foreword the revision of the second volume was commenced by Kaufmann, who died in 1931, and is now in the course of completion by his successor in Göttingen and others. The aim is to preserve the original character of the work so far as possible. The number of illustrations, all black and white drawings in the instalment before us, will be increased and some of the old ones replaced by new. The present instalment deals with the diseases of bones, joints, muscles, tendons, tendon sheaths and bursae. The pathologic anatomy of these diseases receives a thorough, well arranged and well illustrated consideration. The references are collected at the end and cover seventy-two closely printed pages, forming a continuation of references to the first volume. Evidently the second part of the second volume will contain only references.

**Pediatric Surgery** By Edward C. Brenner. A.B. M.D. F.A.C.S. Director of Surgery, Riker's Island Hospital, New York. Cloth. Price \$10. Pp. 843 with 293 illustrations. Philadelphia: Lea & Febiger, 1938.

The use of judicious operative procedures in infants and children presumes an appreciation of knowledge peculiar to that age period. The author has attempted to present this information in a textbook covering pediatric surgery systematically. Practically all the conventional subjects except fractures are included in the scope of the book. Chapters on anesthesia, blood transfusions, cleft lip and palate, thoracic surgery, genitourinary surgery and neurosurgery are contributed by colleagues of the author. These are well done and materially contribute to the book. The author has been left the task of epitomizing the rest of the field of pediatric surgery. This is a difficult assignment in the space permitted in one volume and he has done it creditably. The common surgical conditions in infants and children are for the most part well handled. The section on congenital malformations of the upper part of the gastrointestinal tract could be expanded as this phase of pediatric surgery is a most important one in infancy. Likewise it would seem advisable to present some definite detail on the nutritional aspects of postoperative care in infants. Not all physicians will have the services of a well trained pediatric consultant. The chapter on preoperative and postoperative care is not in keeping with the quality of some of the other chapters. This should be improved in the next revision, as it is an important consideration in pediatric surgery. The book is well illustrated with diagrams and reproductions of photographs. The data are in keeping with current medical thought except for the author's discussion on tetanus. The use of intrathecal therapy as outlined by the author will be questioned by students of tetanus. If the author has conviction on this type of treatment he still owes it to his readers to present the current views. Other omissions appear which will undoubtedly be corrected in the next edition. The author should also give serious consideration to the omission of a well selected bibliography. In spite of his expressed intention of not writing a textbook of encyclopedic character, the reader often would like to go beyond the confines of the text in a particular subject and guidance would be helpful.

**Clinical Atlas of Blood Diseases** By A. Piney, M.D. M.R.C.P. Consulting Physician, International Clinic, Tunbridge Wells, London and Stanley Wyard, M.D. M.R.C.P. Physician, the Royal Cancer Hospital, London. Fourth edition. Cloth. Price \$4.50. Pp. 127 with 42 plates. 38 in color. Philadelphia: P. Blakiston's Son & Co. Inc. 1938.

Many physicians are familiar with this concise atlas of hematology. The present revision comprises rewriting of much of the text and the addition of five new plates. The authors have carefully considered the inclusion of an index but have decided to arrange the table of contents in alphabetical order and append page numbers to the entries in the glossary as a means of facilitating reference. While most physicians will use the book chiefly as an atlas, others will find the epitomized text useful in refreshing themselves on clinical hematology. Under the discussion of glandular fever some mention should be made of the fact that the determination of heterophile antibody is useful when the blood smear is doubtful. The plate on glandular fever would also be more valuable if it pictured more than one type of cell found in glandular fever. Since bone marrow study is being undertaken with increasing frequency, the authors should consider the advisability of including a concise discussion of sternal aspiration and the picturing of some typical smears in normal and disease states in the next revision of their book. This should not cause undue expansion. The present edition is highly recommended to the practitioner and student of medicine. It is one of the most useful books in hematology and compares favorably with any large atlas for clinical purposes.

**Kurzes Wörterbuch zur Geschichte der Medizin** Von Prof. Dr. B. Mayrhofer, Vorstand der Lehrmittelsammlung für Geschichte der Medizin an der Universität Innsbruck. Paper. Price 9 marks. Ip. 224. Jena: Gustav Fischer, 1937.

This is a history of medicine in which subjects, personalities and other material are listed in alphabetical order with from one to fifteen lines on each subject. The American reader will find the book difficult to use intelligently because, for example, the first published medical work is listed alphabetically under the words "Erste medizinische Drucke." Naturally many a great American investigator and contributor to medical science is omitted entirely. There is no mention of Benjamin Rush or of Walter Reed, and three lines are given to Banting. Oliver Wendell Holmes is omitted and fifteen lines are given to Semmelweis. Crawford Long is omitted and William Thomas Green Morton is listed as Wilhelm Morton.

**The Art and Science of Marriage** By Esther Bogen Tietz, M.D. Ph.D. Resident Physician, Longview State Hospital, Cincinnati, Ohio, and Charles Klipp Welchert, Ph.D. Associate Professor of Zoology, University of Cincinnati. With an Introduction by Morris Fishbein, M.D. Editor, Journal of the American Medical Association. Whittlesey House Health Series. Morris Fishbein, Editor. Cloth. Price \$2.50. Pp. 279. New York & London: Whittlesey House, McGraw-Hill Book Company, Inc. 1938.

The writers of this book are a physician, with a special training in psychology, and a biologist. They have approached the problem of modern marriage from these two points of view and have endeavored to provide not only a guide to those about to be married but also an understanding of the chemical, physical, physiologic and biologic factors of the human body concerned in these sex relationships. After three chapters dealing with courtship and marriage they provide an easily understandable outline of the various systems of the human body and of their physiology. The concluding chapters of the book deal with adolescence, embryology, heredity and parenthood. The book is among the sanest and most dependable of all the many in this field that have been recently published.

**Index Catalogue of the Library of the Surgeon General's Office, United States Army (Army Medical Library)** Authors and Subjects. Fourth Series. Vol. III. C. Czypian. [Including] Second Supplement. Fourth Series. Congresses, Tentative Chronological and Bibliographical Reference List of National and International Meetings of Physicians, Scientists and Experts. Cloth. Price \$2.75. Pp. 295, 1,051. Washington, D.C.: Superintendent of Documents, Government Printing Office, 1938.

To those who are familiar with the Index Catalogue this volume covering the letter C needs no further recommendation. The listing of approximately 1,200 congresses, most of them of medical interest, represents an addition which will be widely welcomed. These publications constitute invaluable aids in bibliographic research.

**Psyche and the Physiologists and Other Essays on Sensation** By Edward Guy Dru Drury MD BS DPH Lecturer on Physiology and Hygiene at Rhodes University College Grahamstown South Africa Cloth Price 5s Pp 98 London H K Lewis & Co Ltd 1938

The author of this volume is a general practitioner of South Africa as well as a lecturer on physiology and hygiene. He has a fine sense of humor. Here he has collected six addresses made at various occasions, in which he pokes gentle fun at some of the exaggerations of modern medical science in the fields of psychology, pediatrics and physiology. In the course of his essays he conveys a great deal of practical information. One of the most interesting of the essays is the last, which has the title "Visceral Disharmony," in which he concludes with an analysis of the physiology of sex and love.

**Keats as Doctor and Patient** By Sir William Hale White KBE Consulting Physician to Guy's Hospital London Cloth Price \$2 Pp 96 with 5 illustrations New York Toronto & London Oxford University Press 1938

The poet Keats was slightly over 25 years of age when he died. He had studied medicine for five years and during one of these years had been seriously ill of tuberculosis. Dr Hale-White tells the story of Keats's medical career and of the medical care given to him in his illness. The book affords certain intimate views of the great poet which many a previous biographer has not emphasized. Dr Hale-White is convinced that the medical studies of Keats influenced his writings so little as to be negligible. He is also convinced that the native industry of the poet forced him to work very hard at medicine but that his heart was not really in it.

**Treatment in General Practice The Management of Some Major Medical Disorders** I Articles Republished from the British Medical Journal Second edition Cloth Price 8s 6d Pp 259 with 6 illustrations London H K Lewis & Co Ltd 1938

This is a collection of practical brief articles on the management of some of the major medical disorders that were published in the *British Medical Journal* between 1935 and 1936. The fact that a second edition is necessary bears testimony to its utility. Advantage has been taken of the possibility of revision to bring the new edition down to date and most especially to introduce in the proper sections the use of sulfanilamide. The book deals with diseases of the nervous system, the blood and blood forming organs, rheumatic diseases, diseases of the metabolism and of the kidney, and it may be recommended as a summary of the practice of eminent British physicians.

**The Happy Family** By John Levy MD CM and Ruth Munroe PhD Cloth Price \$2.75 Pp 319 New York Alfred A Knopf 1938

The thesis of this book is that a happy home requires home makers who are "comfortable in their own skins", that is to say, well adjusted personalities. The bickerings, the jealousies, the misunderstandings, the divorces, the infidelities which break up homes are, in the opinion of these authors, but the symptoms of deeper underlying failures to make a satisfactory adjustment to life's problems. The chronic divorcee, flitting from mate to mate, indicates this fundamental unfitness. Immediate circumstances which may seem to determine conduct of this type are in reality but the superficial occasions thereof. The book contains some sensible points of view, which are nevertheless somewhat startling. Settling down to marriage and disillusionment in marriage are sensibly described not as necessary evils but as consummations devoutly to be desired on the theory that it is impossible to maintain forever an artificially high emotional level and that disillusionment, realistically accepted, means getting rid of illusions and facing realities. The failures come to those who cannot achieve these adjustments. The theme is pursued through eight chapters, dealing in turn with how families begin settling down to marriage, the other woman, sexual satisfaction, living together, work and money, children and the difficulties encountered by all children. The book, though published as a collaboration, is written in the first person with a delightfully human in places whimsical, touch perhaps well characterized by the author's remark: "At this point I would like to light my pipe and take a few pages off to chat." The whole treatment of the subject gives this impression, making it an intimate and readable as well as informative piece of work. Some of the views the authors admit are rather advanced, as

for example the belief that, while monogamy is to be preferred, a sensible wife who enjoys her husband's love and understanding may even condone infidelity and the marriage be none the worse for it, provided the underlying cause can be found and remedied, this cause being not necessarily sexual. For men and women whose home life is unsatisfactory this book may well be recommended by the physician as an accessory to whatever medical or psychotherapeutic treatment may be indicated. Dr Levy, who died in 1938, was a psychiatrist. His wife and co-author is a psychologist. The book is a happy blending of their related and coordinated scientific views.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Workmen's Compensation Acts Physicians Presumed to Know Limits of Liability Imposed on Employer by Compensation Act**—A physician, said the Supreme Court of Tennessee who treats an injured workman and who is informed by the employer's insurer that the case is a compensation case and is to be governed by the medical provisions of the workmen's compensation act cannot thereafter recover from the employer a sum in excess of the limit specified in that act. In this case the medical provisions of the workmen's compensation act of Tennessee provided that the total liability of the employer on account of medical services rendered to an injured employee shall not exceed \$100, with an additional \$100 for hospital expenses. The physician attempted to collect from the employer an amount in excess of the \$100 but the Supreme Court limited the physician's recovery to the statutory amount. The physician, in the opinion of the court, was presumed to know the law — *Brandon v Kentucky-Tennessee Light & Power Co (Tenn)*, 116 S W (2d) 1029.

**Dental Practice Acts Statutory Restrictions on Advertising Valid**—The plaintiffs, licensed dentists, sued to restrain the state board of dental examiners from enforcing certain provisions of the dental practice act relating to advertising. From a judgment denying the injunction, the plaintiffs appealed to the court of civil appeals, Texas, San Antonio. The act, among other things, defines as unprofessional conduct advertising by a dentist by means of a large display sign or glaring light sign, either electrical or neon, or by signs containing as a part thereof the representation of a tooth, teeth, bridgework, plates of teeth or any portion of the human head, or using specimens of such in display, directing the attention of the public to any person or persons engaged in the practice of dentistry. This prohibition, the plaintiffs contended, was unconstitutional. But, said the court, the power of the state, through its legislature, to regulate and circumscribe the character of advertising by dentists of their professional services, equipment and facilities is now generally recognized and upheld. The power includes the authority to prohibit the character of advertising condemned by the dental practice act of Texas. This power the court observed, does not rest necessarily on the theory that such advertising must be false or within itself harmful in every case. The true theory is, primarily, at least, that such methods of inducing business are contrary to the well established and universally recognized and respected standard of ethics of an honored and useful profession the maintenance of which will tend to insure competence in individual practitioners and minimize the influence of the charlatan and quack, who, unable to establish or maintain himself on his own merits and virtues, must and does resort to the tricks and devices denounced by the act. It may be the court continued that purely ethical or esthetic considerations will not of themselves warrant legislative interference in setting up and enforcing standards of professional conduct although the tendency among the decisions is to hold

these considerations to be sufficient. Such considerations, however, are proper elements of public policy behind valid legislative acts of control and regulation, they spring from a presumed opinion and demand on the part of the general public that such methods as those condemned by the act here in question are unseemly and demoralizing and actually in derogation of the general welfare, and should be prohibited. Such acts are upheld on the further ground that they are necessary to protect the weak and gullible from their own incapacity, when suffering from real or imaginary ills, to resist alluring promises of cures guaranteed or not, and painless or not, at cheaper prices with better facilities, more skilled treatment and the like.

There was no merit, the court said, in the plaintiffs' contention that the dental practice act offends against the constitutional guaranty of freedom of speech and of the press. The question of freedom of the press was not involved, except as a remote incident of the purpose and effect of the act. The act does not purport to affect the right of the press to publish whatever it sees fit to print, in whatever form or language it chooses. It has been repeatedly and uniformly held that such legislation is not in contravention of the constitutional guaranty of freedom of speech.

The judgment of the trial court, refusing to enjoin the state board of examiners from enforcing the provisions of the act, was therefore affirmed. — *Sherman et al v State Board of Dental Examiners (Texas)* 116 S W (2d) 843

**Evidence Admissibility of Results of Pathometer Tests of Defendant** — The defendant was accused of the crime of robbery. At the trial before the Queens County court, New York, he proffered a witness in his behalf who had subjected him to interrogation under a machine described as a pathometer or psychogalvanometer. The prosecution objected to the testimony of this witness on the ground that the scientific principle involved in the use of the pathometer had not gone beyond the experimental to the demonstrable stage and that it had not received general scientific acceptance.

Evidence was presented to show that the apparatus used was designed for the accurate recording of human emotional reactions. The claim for its accuracy and reliability was based on a study which covered more than 6,000 individual tests. The apparatus, according to the evidence, works on the electrical phenomena developed at the surface of the body during emotional changes. According to the testimony of the witness who applied the test to the defendant there are three of these electrical phenomena, two of which are constant and the third a variable. The variable is eliminated entirely during the examination, and one of the two constant phenomena is selected by means of appropriate contact electrodes. By reason of the human emotional reactions which result on the asking of each question, the witness claimed to be able to separate and detect both the true and the false answers made by the subject. He testified that in actual examinations of persons involved in the forty-nine criminal cases, and in many cases of noncriminal and private nature, the results have indicated 100 per cent accuracy.

Objection to the use of scientific proof the court said, is not at all novel. At one time or another in their development testimony as to fingerprints, as to X-rays, as to handwriting, as to bullet markings and as to psychiatric examinations were all refused admission into evidence. Their gradual admission into evidence came only after many rebuffs and rejections at the hands of various courts. Today their right to admission in evidence is firmly entrenched in law. Yet the deductions of handwriting experts and of psychiatrists are not at all uniform, and frequently experts testifying in courts draw conflicting inferences from their examinations. Despite the fact that such experts frequently differ in their conclusions, their testimony is received in evidence and it is left to a jury to determine which, if either expert to believe. In the present case, the court pointed out, there was testimony that the deductions and the accuracy of the conclusions to be drawn from the examination were undebatable. Both on legal principle and on sound reasoning courts that accept and receive handwriting testimony, psychiatric testimony and other such expert opinion should also admit in evidence, the court thought

testimony of the pathometer test and the results disclosed thereby when a proper foundation has been laid therefor.

The objection of the prosecution to the admission of the testimony was therefore overruled and the testimony was ordered to be received and the jury permitted to evaluate it. — *People v Kenny (N Y)*, 3 N Y S (2d) 348

**Hospitals Sanatorium Not Exempt from Taxation** — The plaintiff sanatorium sued the defendant town to recover taxes paid under protest. The trial court gave judgment for the plaintiff, and the defendant appealed to the Supreme Court of Wisconsin.

A Wisconsin statute exempts from taxation property owned by any educational institution having a regular curriculum and offering courses for at least six months in the year, or by any scientific literary or benevolent association, with certain limitations not here pertinent. The educational institutions covered by the statute, the court pointed out, are those having a regular curriculum and offering courses for six months of each year. The plaintiff had no such curriculum and offered no such courses. Obviously it could not claim exemption as an educational institution. Neither was it a literary institution. The suggestion that the sanatorium was a scientific association was based on the fact that its physicians were engaged in the treatment and study of persons afflicted with mental and nervous diseases, that the knowledge thus acquired was promulgated to the medical profession and that the plaintiff was thus engaged in furthering the science of the care and treatment of mental and nervous diseases. Plainly, the court pointed out, the sanatorium was no more a scientific institution than any hospital or clinic whose physicians disclose their medical discoveries and practices to the profession generally, as physicians as a class take pride in doing.

It was claimed that the sanatorium was a benevolent institution, based on the fact that no person made any profit out of its operation and that a large part of its inmates received treatment and hospitalization at less than cost. Its articles of incorporation too, declared that the "purpose" of the organization of the corporation was "exclusively for benevolent charitable and educational purposes." But, the court said, the sanatorium must be judged by what it actually does rather than by its declared purposes, and the record showed that it receives no patients as charity patients every patient is expected to pay for the service rendered him. No physician or nurse attending the patients and no person administering in any way to them donates his services. The fact that the hospital and its equipment were donated to the corporation did not make it a benevolent institution. The gift was a benevolence but that benevolence cannot be construed as making the hospital a benevolent institution within the meaning of the statute. If so the court pointed out, a gift to a physician to enable him to build and equip a hospital would make the hospital a benevolent institution the gift might be considered a benevolence and the giver a benevolent person, but the hospital would not qualify as a benevolent institution.

The judgment of the trial court, therefore, was reversed, and the case remanded with directions to dismiss the complaint. — *Rogers Memorial Sanitarium v Town of Summit (Iris)* 279 N H 623

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Untoward Effects from Vitamin B<sub>1</sub>**—During the last two years Steinberg has used various preparations of vitamin B complex and vitamin B<sub>1</sub> in the treatment of more than 300 cases of chronic arthritis. During this period herpes zoster has occurred in three patients after large doses of vitamin B<sub>1</sub>. The author was able to produce herpes on two separate occasions in one of these patients. This was not possible in the other two as they refused further treatment because of the pain incident to herpes. Symptoms suggestive of smooth muscle spasm have occurred in other cases. The observations indicate that large doses of vitamin B<sub>1</sub> are capable of irritating the peripheral nerve plates. Therefore one should be on guard in the use of this substance, and when an individual so treated begins to complain of intense burning pain in an unsuspected area the administration of this vitamin should be stopped.

**Rectal Melanosis**—Bacon and Scheffler report twelve cases of rectal melanosis. While the condition is relatively uncommon it is by no means as infrequent as is usually considered. The fact that it can be visualized only by sigmoidoscopy emphasizes the importance of a complete examination of the rectum and sigmoid in all cases coming under observation. Of the twelve patients observed, eight had taken cascara frequently and other laxatives only one was quite emphatic that none of the group had been used. There is little to be said about treatment except that the withdrawal of anthracene cathartics and correction of the constipation will usually result in a disappearance of the pigmentation. It has been estimated that from three to six months is required. This is approximately the period observed in the authors' cases.

**Calcium Gluconate and Kaolin in Dysentery**—Greene and Block used the intravenous or intramuscular injection of 10 cc of a 20 per cent solution of calcium gluconogalactogluconate twice daily complemented by 8 Gm each of kaolin

and calcium gluconate with or without an equal amount of a calcium malt preparation every two hours orally in the treatment of sixty patients with bacillary dysentery. An analysis of the cases revealed a great disparity in the mortality of this and a control group of seventy-five patients. The control group showed a mortality of 24 per cent as compared with 7 per cent in the group treated with calcium. The period of hospitalization was slightly reduced. While the detailed action of the calcium and kaolin treatment used cannot be wholly explained, it seems entirely logical that the beneficial effects obtained are due to a combination of several well known properties of the two substances. The method is not offered as a specific but as a valuable adjunct to other proved medical measures.

**Multiple Necroses of the Spleen**—Schmeisser and Harris divide multiple necroses of the spleen into five groups (arteriosclerotic toxic-thrombotic, angiospastic toxic-thrombotic, purely toxic, arteritic and infectious toxic-thrombotic), review the twenty-seven cases reported in the literature and cite two further cases. The origin of the necrosis itself may be explained by closure of the vessel to a designated region of tissue, relative vascular insufficiency with superimposed tissue injury, or pure tissue injury which by accident was situated in the region supplied by the individual vessel. Nineteen of the twenty-nine cases are observed to be similar to those originally described by Fetus and are associated with renal insufficiency. He ascribed the necrosis to arterial damage superimposed on an arteriosclerosis. The lesions affected primarily the smaller middle size arteries and consisted of hyaline and fatty degeneration with intimal proliferation and often subsequent thrombosis. Lubarsch directed attention to the additional factor of the toxin liberated in uremia and renal insufficiency with which these cases were associated. Geipel and Matthias studied spleens in which there was considerable arterial and venous thrombosis but in which the walls of the vessel were normal. The organs were from patients who died from eclampsia. They agreed with Beneke's idea of the origin of organic injuries through angiospasm caused by the hypothetic eclampsia toxin and followed by secondary thrombosis. These (two) are classed as the angiospastic toxic-thrombotic group. Enzer Lubarsch and Magnus examined spleens from individuals who suffered from profound anemia but no changes were observed in the walls of the blood vessel, either

thrombosis or degeneration. These (three) are probably due to pure tissue injuries which were by chance located in areas supplied by individual arteries, and the etiologic factor is purely toxic. There is one case due to a widespread acute necrotizing arteritis resembling somewhat periarteritis nodosa but in which there was an absence of periarteritic leukocytic infiltration and aneurysm formation. The necrosis was manifest in the spleen, pancreas, kidneys and alimentary tract. This is grouped as arteritic in nature. Four cases are classed as due to infection with the possibility of the toxins liberated coming into play.

**Giant Interstitial Cells of Human Testis**—In a study of the microscopic sections of 721 testes from a series of 470 necropsies on males 18 years of age or over Nelson found in eighty-five testes giant interstitial (Leydig) cells having from four to thirty (usually from eight to ten) nuclei. They were found at all ages and in all sorts of general disease conditions. They do not appear to have been previously described, although their existence has been hinted at. The observations of Berger and others on the "sympathicotropic" or "hilus" cells have been confirmed and extended. It is generally agreed that these cells in the testis are identical with the ordinary interstitial or Leydig cells. The author proposes the name "extraparenchymal interstitial cells" or "extraparenchymal Leydig cells" as best describing them.

**Primary Coccidioidomycosis**—The main endemic focus of coccidioidomycosis in North America is the San Joaquin Valley in California. Dickson states that it is definitely established that infection with coccidioides fungus is caused by the chlamydospores of the vegetative phase of the fungus which in some way gain access to the tissues. There seems to be no doubt that the chlamydospores are carried through the air, presumably associated with dust. When primary cutaneous lesions follow trauma of the skin, as by the prick or abrasion of the skin, undoubtedly the chlamydospores are associated with the dust on the objects causing the primary cutaneous lesions. In general, however, primary coccidioides infection seems to be acquired by inhalation of the chlamydospores, and the development of the primary lesions is in the lungs or regional lymph nodes. The development of the later coccidioidal granuloma is undoubtedly secondary and is caused by migration of the virus to different parts of the body from the primary foci in the lungs or peribronchial lymph nodes, presumably by the blood stream. Infection with coccidioides fungus may be manifested by a primary acute respiratory infection, often accompanied by erythema nodosum from which the majority of patients recover without complication, and a later more or less chronic granulomatous disease, known as coccidioidal granuloma, which may be disabling and has a mortality rate of approximately 50 per cent. It therefore becomes necessary to have a name for coccidioides infection to include both types of illness, and the term coccidioidomycosis has been suggested.

**Myocardial Tuberculosis**—Wilbur encountered a case of congestive cardiac failure in which there was no valvular lesion, hypertension or renal disease. At necropsy there was sufficient

myocardial involvement by tuberculosis to explain the clinical observations in the patient. This and the three other cases are presented to draw attention to tuberculous myocarditis as a primary cause of congestive cardiac failure and to the frequency of tuberculosis involving the cardiac muscle.

**Fever Therapy for Neuropsychiatric Disorders**—During a period of three years Bennett has given 3,539 artificial fever treatments to 766 patients, 244 of whom were suffering from neuropsychiatric disorders. The results on these last patients indicate that fever in itself is the beneficial agent. Future investigations will finally determine whether the method of choice for the induction of fever is biologic, infectious or physical. Combined artificial fever and chemotherapy appears to have certain advantages over malarial therapy for resistant asymptomatic and severe clinical grades of neurosyphilis. Fever therapy is of doubtful value for multiple sclerosis. In obtaining relief from pain in severe neuritic disturbances, artificial fever seems a promising aid. For chronic meningococcal infections, fever therapy may be curative. Artificial fever appears to be the best treatment now available for shortening the course of infectious chorea and other manifestations of the rheumatic state. Experiments in treating toxic infectious psychotic states indicate that fever therapy may shorten convalescence. For such disorders as cerebral arteriosclerosis, functional psychoses and chronic encephalitic states, fever therapy is of no value.

**Anticonvulsive Action of Vital Dyes**—Cobb and his associates gave intravenous injections of brilliant vital red to ten children with various types of epilepsy. The total amount of dye (1 per cent) injected varied from 115 to 1,396 cc. Seven of the ten patients showed temporarily some diminution in the number of convulsions coincidental with the administration of brilliant vital red. Six patients showed sustained improvement, but in the treatment of three of these phenobarbital also was used. However the drug alone had been used before without success. One patient had complete remission of convulsions. Transient albuminuria occurred in four cases. Up to now harmful complications have not been observed. Two patients treated

with neoprontosil have shown marked diminution in the number and severity of convulsions, with no harmful complications. Despite the obvious shortcomings of the study, the authors believe that since in addition to the children four species of animals showed fewer convulsions after the administration of dye it is important to carry on a study of this problem. The results in the ten cases seem to make its trial justifiable, at least in cases of intractable epilepsy.

**Brilliant Vital Red in Epilepsy**—Osgood and Robinson obtained the following results in thirteen institutionalized epileptic boys who received brilliant vital red. 1 Both petit and grand mal seizures were significantly reduced in number in three cases. 2 The number of petit mal seizures only was markedly reduced in three cases, while that of the grand mal seizures remained about the same. 3 The number of grand mal seizures was significantly reduced in one case, in which petit mal seizures had never been known to occur until brilliant vital red was administered. 4 Petit and grand mal seizures were considerably increased in number in four cases. This the authors attribute directly to the dye, since the increased frequency of seizures persisted throughout the period of administration of dye and for weeks or months thereafter. 5 Petit mal seizures were greatly increased, while grand mal seizures remained about the same in one case. Thus they also attribute to the direct action of the dye. 6 No significant change occurred in one case. From their experience the authors believe that the safest and most satisfactory procedure in the administration of brilliant vital red is as follows. At the beginning, from 10 to 15 cc of a 1 per cent solution of the dye is given each day for two or three days, the dye is omitted for a day after these small initial doses, then 30 cc is given two or three days in succession, followed by omission on one day. This procedure has been accompanied by the least amount of renal irritation and other transitory effects.

**Bromsulphalein Test in Liver Function**—Of all the tests yet devised for hepatic function, it is generally agreed that the bromsulphalein dye retention test is as good as any and better than the majority. Because this dye is completely taken out of the blood at the end of thirty minutes in apparently normal persons it is at present considered that any person who at the end of this half hour has no dye has a normal functioning liver. It is with this that Macdonald disagrees, because if this is true it must be admitted that any two livers which have no dye in the blood at the end of thirty minutes are functionally the same and have the same reserve. But this is not reasonable nor is it true. An abnormal liver with its tremendous reserve power can do, if given time, the same work that a normal liver can do. The defect of the test as used at present is this. A normal result does not indicate an absence of hepatic damage because of this great reserve although an abnormal retention means almost definitely a diseased liver. In other words, disease must have advanced to some degree before the test is abnormal, i.e. before it gives a retention at the thirty minute mark, so that early or small amounts or potential disease is passed over and the pathologic liver is considered normal. This is worse than no test at all. If the rate at which the liver takes dye out of the blood can be determined and a graph plotted, it should be possible to

produce a curve that would always be relatively the same for a normal organ (with variations, of course within normal limits). This the author has done by estimating the remaining dye in the blood at intervals of two minutes, by means of a simple three-way valve on a needle remaining in the vein, so that only one puncture is necessary. The curve is plotted with the percentage retention of dye as vertical ordinates and the two minute intervals as horizontal ordinates. The technic of the procedure is as follows. An intravenous needle of short bevel and 18 or 20 gage is introduced into a suitable vein, as for a Wassermann test, the syringe is withdrawn and a three-way Luer valve is attached to the needle in the vein. To this valve is connected a tube leading from a flask of saline or citrate solution which can, by the valve, be directed into the vein or out through the opening which holds the syringe. The handle in the third position allows direct suction through the needle and valve to the syringe into which the blood is sucked, the syringe is detached and the fluid is first directed through the open end, which will prevent clotting in this portion, and then continued into the vein for the two minute period. This prevents clotting in the needle. When it is determined that the fluid is dripping at the proper rate in the vacuum tube and the valve is working properly, 2 mg of bromsulphalein per kilogram of body weight is injected slowly (one minute) into another vein and the first specimen of blood is drawn off in exactly two minutes. This is deposited in a clean dry test tube, allowed to clot and, with the other specimens, centrifuged, and the clear straw-colored serum is examined to determine the percentage retention of dye in that particular specimen. The estimations should not be in numerical order, as this unconsciously tends to determine the next value. The values are then plotted on the graph and joined, to produce the curve.

**Relation of Chorea to Rheumatic Fever and Heart Disease**—Usher determined the incidence of heart disease in fifty-six children presenting a history of one or more attacks of chorea uncomplicated by any other rheumatic manifestations (pure chorea) and compared it with the incidence of heart disease in forty-nine children presenting histories of chorea plus other manifestations of rheumatism (mixed chorea). Definite cardiac involvement was present on admission in 27 per cent of the children with pure choreas, and, if the children with infected tonsils and repeated infections of the upper part of the respiratory tract are omitted, only 14 per cent were associated with endocarditis. In the group of mixed choreas 65 per cent of the children showed heart disease, of which 22 per cent showed a considerable degree of involvement. Valvular heart disease in cases of chorea is due not to the chorea itself but to intercurrent attacks of polyarthritis or severe infections of the upper part of the respiratory tract associated with infected tonsils. It is important as regards treatment and prevention of recurrences to lay more stress on the psychic element in chorea. Removal of foci of infection does not always cure chorea. In the treatment and follow-up there has been a tendency to neglect the basic nervous constitution of the child and its susceptibility to psychic trauma.

**Liver for Patients Intolerant to Arsenicals**—Astrachan determined the effect of injections of liver extract (from 1 to 2 cc half an hour before the arsenical) in forty-eight cases of syphilis in which there was an intolerance to arsenicals. In many cases the injections of liver extract were followed by definite favorable progressive changes in the blood counts and improvement of the patients' general condition. The results of the prophylactic effect in arsenical intolerance seem to indicate that injections of the extract may be of some value in preventing pruritus and in preventing or ameliorating intestinal disturbances and erythema with scaling as well as fixed eruptions but that the injections are of no prophylactic value in preventing the recurrence of exfoliative dermatitis. In view of the results of his investigation the author believes that this problem is worthy of further and more extensive study, including for example the possible advantage of increasing the dosage of liver.

**Coramin in Cardiovascular Disease**—Cowan states that out of a group of seventeen patients suffering from the chronic coronary artery syndrome, observed clinically over a period of several months and treated solely with a 25 per cent solution of pyridine betacarboxylic acid diethylamine, twelve were considerably improved, kept free from symptoms and maintained in reasonably complete economic restitution, three patients were slightly improved and two remained unchanged. As an addition to the armamentarium of cardiac therapy, the substance is suggested in therapeutic doses of from 20 to 30 minims (125 to 2 cc) twice daily, given orally in fruit juices, in the middle aged and younger patient who has shown varying degrees of impaired myocardial efficiency explainable on an arteriosclerotic and atherosclerotic basis. This type of degenerative myocardial disease has been described as (1) the failing heart of middle age, (2) chronic coronary artery disease and (3) multiple myocardial infarction.

**Multiple Primary Malignant Tumors**—In a study of 10870 consecutive necropsies performed at the Cook County Hospital from 1929 to May 1938, Kirshbaum and Shively dis-

covered twenty-five cases of malignant neoplasms, an incidence of 177 per cent among all the malignant growths. There were besides these twenty-five cases 1,288 cases of primary carcinomas causing death, 123 carcinomas were an incidental finding at necropsy. The incidence of sarcomas and malignant neurogenic tumors was not determined in these necropsies. The colon was the site of one of the multiple tumors in thirteen cases, or 52 per cent, the colon and kidney were the most frequent combination involved. The average age was 63.3 years. Seventeen of the patients were men and eight were women. Some persons may be endowed with a congenital, or acquired, predisposition toward tumor formation. These factors may explain the presence of multiple primary malignant tumors in the same individual.

**Caloric Requirements**—In order to estimate the smallest amount of food that is compatible with the health and the occupation of the individual, Rabinowitch studied the effect of restricted diets on 500 diabetic subjects, since these persons must live on diets considerably below their usual habits. He found that bodily equilibrium may be maintained with diets the caloric

contents of which are much below the generally accepted standards. With these diets the average loss of weight was much less than expected theoretically. According to the equation which expresses the law of the conservation of energy in man, it is shown that the amount of energy available for work in the diets of these persons was very small. Since these diets resulted in improvement of health it is necessary to assume that the human body is efficient or that with a tendency toward underfeeding the body has available some unrecognized source of energy. Since the average diet contains sufficient energy (about 2,500 calories) to do about 3,000,000 foot-pounds of work, independent of the basal metabolism requirements the human machine appears to be very inefficient under ordinary conditions. The alternative therefore appears to be that, with a tendency toward underfeeding, the body has available some unrecognized source of energy. That the body can at times use energy which is ordinarily wasted as heat is suggested from the reduction of the specific dynamic action of food during work.

**Extrapleural Pneumothorax.**—Monod believes that artificial extrapleural pneumothorax is an operation of choice because it is a less traumatizing operation than thoracoplasty, it can be done in one stage, it is less painful and more easily tolerated and its action approximates mostly that of an artificial intrapleural pneumothorax, which is the most physiologic intervention on the lungs. Artificial extrapleural pneumothorax may be used in urgent cases because its action is frequently as rapid as that of an artificial intrapleural pneumothorax. In pregnancy, for example, when one must act quickly, the artificial extrapleural pneumothorax is indicated. It is essentially a conservative operation as, given similar lesions, it permits a more selective collapse than does the most conservative thoracoplasty. It is the operation of necessity in advanced cases in which the choice of treatment is limited and thoracoplasty cannot be undertaken. The fact that extrapleural pneumothorax can be used in urgent cases makes it a procedure with immense possibilities—unless the results in the future should prove the contrary.

**Sulfanilamide and Experimental Tuberculosis.**—The experiments on guinea pigs that Ballon and Guernon report indicate that under the conditions of their study sulfanilamide exerts an inhibitory effect on the development of tuberculosis. Their observations confirm those reported by Rich and Folliis. The authors commenced treatment with sulfanilamide five and ten days after infecting the guinea pigs. Repeated relatively small doses of the drug were tolerated better than larger doses given less frequently. Daily doses of from 340 to 380 mg. of sulfanilamide proved adequate yet not too toxic for most guinea pigs weighing 350 Gm. An inhibitory effect on the tubercle is possible even though treatment is interrupted. The effect is shown by the fact that the local lesion in the treated animal is less necrotic; similarly the regional lymph nodes are less swollen and less indurated, the spleen is considerably smaller and usually free of macroscopic tuberculous lesions. In addition there is a relative absence of generalized tuberculosis in the treated animal. On the other hand not only does the untreated

animal have generalized tuberculosis but, in addition, the local lesion is more extensive, more necrotic and the regional lymph node is much larger and more swollen and indurated. The spleen of the untreated guinea pig is not only large but also exhibits macroscopic tuberculous lesions. The experimental results do not permit clinical application.

**Neurogenic Diseases of the Bladder.**—The treatment of neurogenic diseases of the bladder is one of the most indefinite and, in some instances, most unsatisfactory problems with which the urologist has to deal. Herbst states that the investigation of patients with dysfunction of the bladder should consist of a careful history, thorough physical examination, urinalysis and renal function tests, x-ray examination of the kidneys, ureters and bladder, careful catheterization, cystoscopy and neurologic examination. He discusses briefly the treatment of cerebral and spinal cord tumors, tabetic bladders, temporary paralysis of the detrusor muscle incident to labor trauma, painful contraction of the wall of the bladder, spasm of the vesico-ureteral junction and painful cystitis, from which he concludes that a conservative attitude should be maintained and the simpler measures employed before resorting to renal sympathectomy, ureteral neurectomy, presacral neurectomy and sacral resection of the ganglions. In rare instances, spinal injection of alcohol or chordotomy may be employed. Whenever marked deviations from a normal neuromuscular functional balance are recognized, a thorough neurologic examination is imperative.

**Fever Therapy in Resistant Gonorrhea.**—Owens and his co-workers present the results of artificially induced fever in eleven patients with gonorrhea who were intolerant to sulfanilamide. Each patient had received sulfanilamide therapy in fairly adequate dosage. Some had had two or three courses of this medication. Each patient had persistently positive smears for gonococci following the sulfanilamide therapy. Several had developed epididymitis or arthritis during the course of treatment. Each patient entered the hospital and received a preliminary three hours in the Kettering hypertherm during which time his temperature was raised to from 103 to 104 F. This preliminary heating was given largely to accustom the patients to lying in the warm cabinet and to quiet their fears. The following day each patient received ten hours of artificial fever at from 106 to 107 F. He then remained in the hospital one or two days after this treatment, during which time check-up examinations were made. He was then dismissed but remained under observation for repeated check-up examinations. Ten of the eleven patients were cured (entirely free of all clinical symptoms and signs, and repeated examinations by smears have failed to show gonococci after periods of normal behavior as regards alcoholic and sexual stimulation) by the single fever treatment. Although the remaining patient was not cured by the fever session apparently the organisms were made more susceptible as a second course of sulfanilamide succeeded in curing him.

**Endometrial Patterns and Menstruation**—Kotz and Parker studied by endometrial biopsy fifty cases in which functional bleeding was the chief complaint. In these cases the endometrium exhibited all degrees of normal differentiation as well as aberrations manifested by hyperplasia, hypoplasia, persistent or delayed reactions or senility in either the follicular or the luteal phases of the cycle. There were nine cases in which the endometrium was of the follicular type. There was bleeding in five from two to three weeks, while in three there was prolonged, acyclic bleeding. In all cases estrogen was demonstrable in the blood, although there was a tendency for it to be decreased in quantity below normal. There was no case of excessive gonadotropic substance. There were fourteen patients who exhibited follicular hyperplasia of the endometrium. All of these had acyclic, either profuse or prolonged, bleeding. The test for the estrogen content of the blood was positive in all these cases with a tendency for increases above normal. There was no incidence of excessive gonadotropic substance. There were six cases in which the endometrium exhibited a delayed postovulatory reaction, subnuclear vacuolization. In five cases there was evidence of previous excessive proliferation, in only one case was the condition apparently normal. In one case bleeding was acyclic and profuse, while in five it was cyclic with the interval ranging from fourteen to twenty-eight days. The blood estrogen was negative in two, strongly positive in two and normally positive in one. There was no incidence of excessive gonadotropic substance. The authors have encountered what seems to be an exaggeration of the early secretory reaction of the endometrium in eight cases, all with cyclic bleeding, but with shortened intervals in four cases. All these women complained of profuse or prolonged bleeding. Estrogen was demonstrable in all and there was a tendency for it to be increased above normal. In no cases was there an excess of the gonadotropic substance. It would seem that this type of endometrium is an early secretory reaction in which bleeding has been initiated in the presence of a high level of estrogen and before the corpus luteum has reached its full maturity. In thirteen cases the endometrium showed variations of the late secretory reaction. In nine cases there was cyclic but profuse bleeding, while in the remainder it was acyclic and prolonged. There was no definite correlation between the character of the bleeding and the type of endometrium encountered. The blood estrogen was positive in all cases and the gonadotropic substance was negative. The series as a whole represented a younger age group (from 16

to 45) than that usually encountered in cases in which follicular cystic hyperplasia was the characteristic condition. It would seem that there are three degrees of endometrial abnormality which correspond to the degree of ovarian failure. First there is the type in which an abnormal secretory reaction is present and which may be the forerunner of the next type, in which follicular endometrium is characteristic. Both of these types occur during the reproductive stage of life. The third type is the hyperplasia occurring after the menopause. The first two types are almost without exception benign, while malignant changes in the third type occasionally occur. The factors or factors which account for this transition cannot be explained.

**Sulfanilamide in Scarlet Fever**—Wesselhoeft and Smith epitomize that sulfanilamide therapy of scarlet fever in the eruptive stage in the accepted dosage does not reduce the toxicity as manifested by the intensity of the eruption or the duration of the fever. Sulfanilamide therapy, given during the initial stage of the disease, did not reduce the incidence of complications. However, in cases in which the drug was continued longer the incidence was markedly reduced. Since the usual invasion of the scarlet fever streptococcus takes place in the upper part of the respiratory tract and this primary toxic phase is not influenced by sulfanilamide therapy, it is reasonable to infer that the drug will not be efficacious in the septic complications involving the respiratory tract. This inference appears to be substantiated by clinical results, although satisfactory data on this point are not as yet available. Sulfanilamide therapy appears to be useful in certain infections of the mastoid cells, but the possibility of an associated infection of the blood stream through destruction of bone may be a factor. Infections of the blood stream and meningitis are indications for sulfanilamide therapy. In these two complications the results of its administration have lowered the mortality. Bacteriologic evidence suggests that the use of sulfanilamide in the last week of convalescence from scarlet fever does not reduce the carrier rate through the eradication of hemolytic streptococci from the nose and throat. The use of sulfanilamide as a prophylactic in nonimmune contacts is a problem for carefully controlled investigations.

**Incidence of Rheumatic Infections in Oregon**—The investigations of Bilderback and Overstreet agree with others that the universally recognized manifestations of rheumatic infection, arthritis and carditis may occur in the same patient, superimposed on or at a varying time interval before or after chorea. However, rheumatic carditis is not found as frequently in the person with chorea alone as in the person with both chorea and rheumatic involvement of the joints. Rheumatic fever and chorea constituted 3.46 per cent of the 4,197 medical admissions (116 patients) to Doernbecher Hospital during a period of five and one-half years. Some of these were admitted for recurrence of the disease on several different occasions. The youngest patient was found to be ill at the age of 20 months, but the diagnosis was not made until death occurred at 3 years of age at which time healed rheumatic endocarditis was discovered. Rheumatic fever is a seasonal disease to some extent, having its greatest incidence in the winter and early spring months. However, no month is exempt and the curve of monthly incidence is roughly parallel to that of precipitation and inversely proportional to the average normal temperature but not sufficiently so to permit any definite conclusions. The presence or absence of the lymphoid tissue of the pharynx has been the subject of considerable investigation. Recent work tends to suggest that the popular surgical procedures of a few years ago are less often performed in the presence of acute infection. Of the 116 patients studied, thirty-nine had had adenotonsillectomy performed prior to the first attack, while seventy-one had not undergone the procedure. In six no statement was obtained. No conclusions are to be drawn from this except that tonsillectomy seems to reduce the incidence appreciably.

**Oxygen Therapy**—Davies states that, until such time as the clinician and the layman understand that oxygen therapy is a perfectly logical, practical procedure and an excellent symptomatic treatment, one will labor under a definite psychologic handicap. It is unfortunate that the reaction to oxygen therapy in the mind of the layman is either that oxygen is life giving, a miraculous panacea, or more frequently that oxygen is to be employed when all hope is lost—a symbol of the inevitable approach of death. Oxygen therapy is a decided adjunct to modern methods of treatment. It should be employed early, continuously and in a concentration adequate to overcome anoxemia. In the operation of any type of oxygen tent, cer-

tain practical points should be emphasized. 1 The apparatus used must produce and hold the desired oxygen concentration. 2 There is only one way to know the exact concentration of oxygen in the tent and that is by actual analysis. 3 The need for a soda-lime absorber for carbon dioxide is more theoretical than actual. 4 The concentration of oxygen should be kept at or above 45 per cent and is to be increased whenever necessary to overcome anoxemia. 5 The temperature and humidity gages should be kept inside the tent and it should be taken and recorded every two hours. It is a dependable check on the operation of the tent. 6 The temperature in the tent should be kept between 55 and 65 F for adults and from 65 to 70 F for infants and children and the humidity between 30 and 60 per cent. 7 The intern, nurse, orderly or relative (in the home) should know the correct method of changing oxygen tanks as reducing valves may be easily ruined by carelessly changing high pressure tanks. 8 The physician should accept complete personal responsibility for oxygen therapy. Oxygen therapy is medical treatment and should be kept out of the hands of commercial enterprises. 9 The concentration of oxygen in the tent should be brought down before the patient is changed to room air for any considerable period. Oxygen therapy has long passed the probationary period and is of considerable importance in the treatment of all forms of anoxemia.

**Fluid Balance in the Puerperium**—Crabtree presents a group of heretofore unassociated observations which indicate that the pregnant woman fails to eliminate fluids as adequately as does the nonpregnant one and that the storage of fluids in the blood stream and tissues of the body in the course of a normal pregnancy may and probably does, without production of anasarca, take place elsewhere in the body besides in the products of pregnancy. He concludes that pressure of the gravid uterus on the ureters is not adequate to explain the changes in the renal tree which commonly occur in pregnancy. A double etiology for these changes, if considered both as to nature and as to

degree, should be accepted for human beings. An endocrine factor should be given equal if not greater significance than the pressure factor. There are several established lines of evidence which indicate that fluid storage in the course of pregnancy should occur regularly and in all cases. In all except one of fifty-four cases that the author studied over the average fourteen days that women in the puerperium stay in the hospital, except in five febrile cases, there was an output of urine in excess of fluid intake too large and of too long duration to be considered accidental. If fluid losses attendant on delivery and the puerperium, purely obstetric in nature, and lactation are included the foregoing figures will be greatly exaggerated. Medical, surgical and urologic diseases, when they develop in the course of either pregnancy or the puerperium, should be considered in relation to a disturbed fluid balance and not by the fluid balance in nonpregnant women.

**Bone Sarcoma**—Simmons reports the results of treatment of forty-seven patients with primary malignant tumors of the long bones, excluding plasma cell myeloma. These patients were seen during a period of thirteen years (1920 to 1932). No patient is considered cured unless he is living without evidence of disease five or more years after treatment. It appears that the prognosis is far from hopeless when patients are treated by radical surgery. The tumors in which relatively adult tissue such as fibrous tissue and cartilage, predominated did not form metastases for some time after the tumor was demonstrated clinically, and the patients were usually cured by complete removal of the growth. The duration of the tumor before treatment undoubtedly has a bearing on the result in a given case, although if these cases are considered as a group this is not so. The prognosis appeared to be worse in the cases of short duration, but it was found that the duration in the majority of low malignant tumors in which cures were obtained was appreciably longer. The value of preoperative radiation treatment is problematic. It was not employed in any case in the present series, for the time element was considered more important. Radiation undoubtedly affects the cells profoundly but apparently does not destroy the tumor. There is no instance of cure by radiation alone of a proved case of osteogenic sarcoma in the Registry of Bone Sarcoma. The surgical procedure adopted whenever possible was a biopsy and immediate amputation if the tumor was reported to be sarcoma. There is no way by which the various types of osteogenic sarcoma can be distinguished clinically with any degree of accuracy, although occasionally the character may be suspected. In persons more than 50 years of age the tumor is usually secondary to Paget's disease of the bone or of the chondral type. The eight patients with Ewing's sarcoma are all dead. Of the twenty-eight patients with osteogenic sarcoma in which amputation was done, eleven are living without disease five or more years after operation. The prognosis depends more on the amount of differentiation of the cells comprising the major portion of the tumor than on any one other factor. If the tumor is composed in large part of adult fibrous tissue or cartilage, the prognosis is better than if the cells show marked anaplasia. The five patients in whom fibrous tissue predominated, treated by amputation, are well. Of seven on whom amputation was done and cartilage was the predominating tissue, five patients are well. Of sixteen patients who required amputation and who may be placed in an anaplastic group, one is well. Of two patients with reticulum cell sarcoma in which amputation was done, one is well fourteen years later and one died twelve years later of a tumor of another bone, the character of which was not determined.

**Treatment of Acute Osteomyelitis by a Sulfanilamide**—Mitchell treated five cases of severe acute osteomyelitis with a sulfanilamide preparation (ultron) in addition to the ordinary local treatment. To young children he gave one tablet (7½ grains, or 0.5 Gm.) every four hours. The period over which it has been administered has varied up to several weeks. All these patients have done exceptionally well, particularly two patients in whom the condition seemed absolutely hopeless. All of them had severe septic osteomyelitis and not the milder type sometimes seen.

**Epidemic Myalgia**—Howard reviews briefly the literature of epidemic myalgia and gives an account of five cases occurring in one household. These cases closely followed the clinical picture described by Sylvest, the main features being a sudden onset with abdominal pain and malaise, the pain moving to the chest, particularly the right costal margin, on the second day and later diffusing all over the chest and shoulder. The chief disabilities are intermittent attacks of malaise for about a week, combined with the inability to laugh or take a deep breath without excruciating pain in the chest, also the frustration, in spite of a strong urge, of being unable to defecate satisfactorily. At about the same time as the foregoing cases occurred there were admitted to the local hospital more cases than usual, perhaps, of appendicitis that never came to operation. Unfortunately these were not investigated with myalgia in mind.

**Sulfanilamide in Acute Surgical Infections**—Ray and his associates used derivatives of sulfanilamide in 100 consecutive cases of acute surgical infections. In erysipelas and streptococcal septicemia, prontosil red may be regarded as a specific. In none of these conditions need antistreptococcus serum be given. In the authors' experience, prontosil red preparations appear to be of greater efficacy than prontosil album and allied sulfanilamide

preparations In acute funiculitis and epididymo orchitis of filarial origin a dramatic result is usually achieved, even in those cases in which no secondary bacterial infection could be discovered In acute urinary infections, gonococcic urethritis and acute staphylococcic infections the drug has proved to be of great value In their experience, treatment by intramuscular injections is best combined with oral administration of prontosil red tablets In about 6 per cent of cases the latter may give rise to vomiting or anorexia, when it may be replaced by prontosil album tablets Certain drugs are to be avoided during prontosil therapy In a series of seventy consecutive cases, excluding six late cases of sinus thrombosis and septic bronchopneumonia complicating facial cellulitis, the mortality rate was 47 per cent There were no deaths in a subsequent series of thirty consecutive cases In erysipelas the highest average temperature was 102.2 F, which was brought down to normal in 24 days In facial cellulitis the normal was reached on the fourth day

**Blood Culture in Cholera**—deMonte and Gupta examined the blood of twenty-six cholera patients for the presence of vibrios The blood was collected as early as possible after the onset of symptoms, in from three to nine hours Vibrios were not isolated from any of the samples, confirming the observations of Greig, who was unable to isolate vibrios in the blood during life

**Bactericidal Power of the Blood**—Miles and Misra believe that the survival rate of a measured inoculum of *Staphylococcus aureus* in a standard volume of defibrinated blood is a reliable quantitative measure of the bactericidal power of blood The number of viable organisms in the inoculum and in the blood-bacterium mixture may be estimated by counts of colonies developing from measured volumes of the fluids permitted to fall on the surface of solid mediums Fildes' agar was the most suitable medium for this surface viable count The number of colonies growing from a sample of a blood bacterium mixture may be reduced not by killing of the individual cocci but as a result of their aggregation either by agglutinins in the blood or in the cytoplasm of leukocytes that are phagocytic but not bactericidal It appears that these mechanisms are unlikely to operate in blood-bacterium mixture containing relatively few organisms, in such mixtures the survival rate is a reflection of the killing power only The immunologic significance of the survival rate has not been investigated but the range of values for healthy human adults differs significantly from that for sufferers from chronic staphylococcic infection

Trichlorethanol on Trial C L Hewer and D Belfrage—p 1290

**Percutaneous Absorption of Testis Hormone**—Foss studied the potency and the optimal dosage of the percutaneous application of testosterone propionate in a fatty vehicle and an alcoholic solution in a postpuberal eunuch, a eunuchoid and a patient with delayed puberty He compares their effects with those of a solution of testosterone in alcohol This method of giving testis hormone is effective and simple but a larger dosage is required than when the medication is given by injection An ointment containing 25 mg of testosterone propionate per gram in collapsible tubes of 2 Gm is recommended for practical use as the most efficient means of percutaneous androgen therapy at present available Much more rubbing is necessary before the greasy ointment is worked into the skin and disappears than when applying the alcoholic solution, which evaporates rapidly and gives the patient the impression that the medication is completely absorbed Allowing, however, for this wastage, the local effect, e g on hair growth and development of the penis and larynx—is greater with percutaneous medication than injection, which bears out the original experiment on the capon's comb There is no doubt also that the maintenance of prostatic and vesicular secretion is sustained by the percutaneous route, for the eunuch has a normal ejaculate after only four months of percutaneous application This method of application is most acceptable to the patient who desires a maintenance dosage, whereas subcutaneous injection will be reserved for initial intensive therapy or for a periodic depot dose

**Treatment of Lupus Erythematosus**—Chajes treated thirteen patients with long standing lupus erythematosus with a complex carbamide compound of trisulfonic acid (Bayer 205) Only two of the patients gave a history of having the disease less than one year In a few cases a mild ichthammol-resorcin paste was used to relieve the itching which sometimes occurred at the site of the intravenous injection of the 10 per cent solution of the drug A cure was obtained in nine of the thirteen cases and considerable improvement in four Recurrences after the first injection were observed in six cases but were always favorably influenced and usually cured by further injections The author observed four cases for more than a year and in only two of these could he diagnose a recurrence within the period of observation

**Cerebral Paratuberculosis**—Cohen and Wood draw attention to a disturbance of the central nervous system sometimes observed in children and young persons suffering from pulmonary tuberculosis It seems to be due to an acute exudative reaction localized in the cerebral meninges Though associated with tuberculosis and apparently a reaction (specific or allergic) to the tuberculous virus, its fleeting and benign character clearly distinguish it from tuberculous meningitis The authors have seen five cases in the last two years The ages of the patients ranged from 6 to 20 years Four were suffering from pulmonary tuberculosis of the adult type and one from generalized tuberculosis following primary infection In each instance the pulmonary disease has been mainly exudative and the symptoms of comparatively recent origin The principal symptoms were headache and lethargy or drowsiness These preceded or accompanied the onset of fever Physical signs were few, apart from sluggish reactions of the pupils and sluggish or absent knee jerks during the attack In three instances a rash was observed

—erythema nodosum, a generalized simple erythema and a mixed papular and morbilliform eruption. Lumbar puncture yielded cerebrospinal fluid which was under pressure but was clear and sterile and showed no cellular or chemical abnormality. Its withdrawal was followed by a notable relief of the headache. Recovery was uneventful and took from seven to fourteen days. One patient had a second attack after a quiescent interval of several months but this was again followed by a spontaneous recovery.

**Vascular Reactions to the Contrast Bath**—Woodmansey and his associates describe a contrast bath which allows the cutaneous temperatures of an immersed forearm and distal parts to be taken. It was found that the best reaction (active contraction and relaxation of blood vessels and increased blood flow) is obtained when hot water is applied for six minutes and cold water for four minutes. Patients with rheumatoid arthritis gave poor reactions, probably because the blood flow is attenuated in the affected limbs because of disuse. Some healthy women also gave feeble reactions, probably because of an inherent lack of adaptability in their peripheral circulation. This inherent defect may increase the susceptibility to rheumatoid arthritis but is not the primary cause. The greater incidence of vascular deficiency in women may account for the prevalence of severe and intractable forms of rheumatoid arthritis in them. The authors suggest that the so-called primary rheumatoid arthritis with vascular signs and symptoms is rheumatoid arthritis (probably of infective origin) in a person with a constitutional vascular defect. Disease brings the vascular failure into greater prominence.

**Nasal Spraying and Diphtheria Immunization in Prophylaxis of Poliomyelitis**—Dwyer states that nasal spraying with zinc sulfate solution was begun at Hindmarsh Dec. 22, 1937, soon after the commencement of an epidemic of poliomyelitis, and was continued at intervals until February 3. Of the 251 children treated 121 received two treatments at an interval of approximately three weeks. Treatment was continued as long as required and ceased Feb. 3, 1938. Of the 251 children 126 had been immunized against diphtheria. The author draws no conclusion concerning the efficacy of the method. The preliminary spraying with a solution of ephedrine and pontocaine greatly facilitated the procedure, and the frequency (62.5 per cent) of anosmia among those treated was higher than in many previous reports. In towns in which a substantial proportion of children were immunized against diphtheria, these children were significantly less likely to contract poliomyelitis than their unimmunized companions of the same age group.

\*Lymphangiography in the Living. Method, Results and Applications. H. Monteiro—p. 241

\*Action of Derivatives of Sulfanilamide in Postpartal and Postabortal Infections. J. Lambillon and A. Lejeune—p. 252

**Lymphangiography in Living Animals**—In spite of the condemnation of thorium dioxide sol by some investigators on account of its harmful effects on the hematopoiesis, on the liver and on the spleen, Monteiro says that the doses necessary for the injection of a section of the lymphatics are generally small and well below those that are injected to obtain roentgenograms of the liver, the spleen or the arteries. Usually 4 or 5 cc of the liquid is sufficient to obtain, after the injection of the popliteal lymphatic, a picture of the iliofemoral vessels and of the entire thoracic duct, in a dog weighing from 10 to 15 Kg. The technic of the injection is much like that used for the injection of the lymphatics in cadavers. Of the numerous lymphangiographies that were made on guinea pigs, rabbits, cats and dogs the author discusses only a few. He shows that the intradermic injection of the opaque substance into the external ear of a dog brings into evidence the superficial lymphatic vessels from the auricle to the lymphatic vessels at the base of the neck, corresponding to the supraclavicular group in man, that an injection into the skin of the toes shows the lymphatic vessels of the leg and thigh and the popliteal lymphatic, that an injection into the testicular albuginea shows the testicular lymphatics. In discussing the applications of this method, the author says that the experimental and clinical studies of Leriche having demonstrated that sympathectomies have a favorable effect on the reestablishment of the arterial circulation, it seems justified to inquire whether interventions on the sympathetic have an identical influence on the reestablishment of the course of the lymph stream. However, before giving his attention to the action of sympathectomies on the lymphatics he takes up the reestablishment of the circulation after ligation or section of the lymphatic vessels. Among the roentgenograms reproduced in the text there is one of a dog in which thirteen days previously the left jugular trunk had been ligated. The opaque substance injected into the lymphatics on the side on which operation was performed had passed through the well developed median anastomoses and had filled the lymphatics and the jugular trunk on the opposite side. Studying the influence of sympathectomies on the reestablishment of the interrupted lymphatic circulation, the author finds that sympathectomies favor, as in the case of the arteries, the reestablishment of the lymphatic circulation after interruption of the large trunks by the development of a large number of derivative passages and, perhaps, by better conditions of nutrition in the connective tissue which accelerate the reconstruction of the interrupted lymphatic vessels. Discussing the restoration of the lymphatic circulation after cutting of the ganglions, the author directs attention to the roentgenogram of a dog which twenty-one days before had undergone ligation of the left jugular trunk. The liquid injected into the jugular lymphatic of this side had not descended in the jugular trunk but had mounted and had filled the fine vessels which had conducted it to the opposite side, thanks to dilated median anastomoses. Consequently these thin vessels, at that time efferent vessels of the lymphatic, must represent normal afferent vessels of the jugular lymphatic. In experiments on the transplantation of lymphatics it was found that the roentgenologic visualization demonstrates that autoplasmic transplantation of capsulated lymphatics succeeds only in young animals. In the last part of his extensive report the author shows that the methods described are of value from the anatomic and physiologic as well as the clinical point of view, particularly with regard to the treatment of cancer.

**Sulfanilamide in Postpartal and Postabortal Infections**—Lambillon and Lejeune say that from the end of 1935 sulfanilamide preparations were used at their clinic in abortions in which infection is always to be feared. When it was found

that the preparations were well tolerated they were employed also in postoperative complications anginas, influenza and diverse infections. During the years 1936 and 1937 the authors had occasion to use sulfanilamide preparations in all obstetric cases in which long duration of labor or multiple obstetric maneuvers performed outside the clinic justified the fear of a puerperal infection. With this preventive measure only one fatality resulted in 827 confinements. Cases of mammary congestion after delivery likewise proved the anti-infectious action of the sulfanilamides. In order to be able to evaluate the action of sulfanilamide preparations objectively, the authors treated for a time only alternate cases, irrespective of their severity, with sulfanilamide, giving eight tablets daily. They show two tables listing the temperatures (on admission, the maximum after onset of the treatment and the final), the degree of leukocytosis and the duration of the febrile period. One table gives the records of the nine cases in which the sulfanilamide was omitted and the other one gives those of sixteen cases in which it was administered. That the second group is larger is due to the fact that after a certain time the sulfanilamide was again administered to all patients. A comparison of the two tables reveals that the cases treated with sulfanilamide took a more favorable course than those in which this treatment was not employed. The temperature usually decreased more rapidly in the patients who were treated with sulfanilamide than in those who were not. If complications such as Douglas abscess or ovarian abscess evolve in the cases in which sulfanilamide is administered, the subjective symptoms are slight. The authors gained the impression that sulfanilamide therapy favors localization of the infections and their passage toward suppuration. They cite several case histories which illustrate the tendency to localization during treatment with sulfanilamide. In the conclusion they stress that the preparations which they employed were well tolerated. Even in prolonged administration they did not observe complications. In view of this harmlessness and the favorable action, they recommend sulfanilamide as a valuable adjuvant in the preventive and curative therapy of puerperal and post-abortion infections.

\*Raynaud's Disease. Therapeutic and Pathologic Considerations on Basis of Thirteen Cases. P. Wertheimer and M. Berard —p. 737  
Technic of Total Extrafascial Apicolysis. M. Iselin and R. Dubau —p. 748

Relapsing Dislocation of Hip. C. Lenormant —p. 778

**Raynaud's Disease** —Wertheimer and Berard describe thirteen cases of Raynaud's disease in which they resorted to surgical treatment. In seven cases they performed periarterial sympathectomies and in the other six cases they made interventions on the cervicothoracic sympathetic nerve ganglions. Six of the periarterial sympathectomies were successful and one was not. However in the six cases the cure was not absolute, the patients themselves estimated their improvement at about 50 per cent. The attacks still recurred but were less frequent and not so severe during the cold season there was some aggravation. Pains were absent during the summer and were bearable during the winter. Discussing the results obtained with the operations on the cervicothoracic sympathetic ganglions the authors say that in one case they resorted to inferior cervical ramisection. Complete cure was obtained in this case. One of the two patients who were subjected to stellectomy was completely cured and the other had 50 per cent improvement. Substellate resections on the thoracic chain were made in three cases. Two of these patients were completely cured but the other one failed to obtain any relief. Thus of thirteen cases of Raynaud's disease in which surgical operation was performed four were completely cured seven were greatly improved and two were not improved. The authors think that no medical treatment can rival these results of the interventions on the sympathetic but although their efficacy is recognized the value of the various technics is still under discussion. The authors are in favor of interventions on the sympathetic chain the results of which are better than those of periarterial sympathectomy. Moreover studies by

Leriche and others have proved that of the different technics those on the lumbar sympathetic are superior to those on the cervical chain or the stellate ganglion. Discussing the pathologic problem of Raynaud's disease, the authors point out that three hypotheses have been advanced. The oldest one, already suggested by Raynaud, assumes that the disease is purely a vasomotor problem, another one supposes the constant existence of endarteritic lesions, the third one invokes a myoarterial origin. Evaluating these different theories, the authors say that the theory which assumes a myoarterial origin lacks anatomic demonstrations and the results of the sympathetic interventions likewise do not speak in its favor. On the contrary, their efficacy seems to demonstrate that the disorder is of a vasomotor type in which a vasoconstrictor hypertension predominates.

\*Survey Over Results of Interventions Practiced in Forty Nine Cases of Nephro-Angiosclerose (Permanent Hypertensive States with Renal Lesions of Arterial Origin). H. Chabanier, P. Gaume and C. Lobo Onell —p. 1818

**Interventions in Nephro-Angiosclerosis** —Chabanier and his associates discuss the hypertensive states, which they prefer to designate as nephro angiosclerose. After citing the opinions of Volhard and Fahr, who differentiated between the benign and malignant types of nephro angiosclerosis, they review the anatomic and the clinical aspects of the malignant type of nephro-angiosclerosis and show that the benign and malignant forms are two entirely different disease entities. They also differentiate two types of permanent arterial hypertension: the form without renal symptoms and the hypertension with nephritis. To be sure, these two types do not correspond to morbid entities; they have only the value of nonspecific syndromes, because they may be the expression of essentially different morbid processes. Even solitary hypertension can be the manifestation of benign or malignant nephro-angiosclerosis. In hypertension with nephritis the situation is similar. This syndrome may be the expression of two essentially different morbid processes, that is, of malignant nephro-angiosclerosis and of a diffuse chronic glomerular nephritis. In general, all cases of hypertension in persons beyond the age of 60 can be considered as the manifestation of a benign nephro angiosclerosis, however, solitary hypertension developing before the age of 60 is likely to correspond to the initial stage of a malignant nephro angiosclerosis, especially when the subject is quite young. The authors say that therapy involves two factors: dietetic measures and medicaments. The regimen consists in the restriction of liquids, of the quantity of foods and, in case of secretory disturbances of the kidneys, in the restriction of nitrogenous foods and finally in dechlorination. Medicaments aim at the reduction of the hypertension or at least of its functional manifestations. Others are directed at the compensation of the results of the insufficiency of the left side of the heart and still others are to facilitate the renal elimination. After citing shortcomings of the medical treatment the authors give their attention to the surgical procedures. Their experiences on the surgical treatment of nephro angiosclerosis are based on sixty-five cases, but only forty-nine are considered here because in the others the operation was too recent to permit a conclusion. The methods utilized in these cases have been simple decapsulation, renal enervation combined with decapsulation, adrenalectomy, splanchicectomy, and splanchicectomy combined with the resection of the aorticorenal ganglion as well as of the nerves going to the renal pedicle and to the adrenals eventually combined with renal decapsulation. The general condition of the patients in the terminal stage of the disease when operated on was poor: there was marked renal insufficiency, the hypertensive syndrome was severe, there was decompensation of the left side of the heart and a fatal outcome was near. Consequently the authors considered an intervention justified in spite of the risk that was involved. Every improvement, even if only partial or of limited duration is priceless for these patients, and such a relief always follows the operation. More than that, there are even cases in which the improvement of the clinical syndrome is so considerable that the patients can resume an active life. To be sure

such a result is as a rule only temporary, it hardly extends beyond several months or a year and a half. In patients who were operated on before the terminal stage, that is during the stage of solitary hypertension or during the stage of hypertension with nephritis, the general resistance was usually such that they tolerate the different operations. However, vascular collapse must be watched for. The authors gained the impression that the diverse methods produce analogous and almost equivalent results. Usually the arterial tension decreases immediately, but after several months there is often a renewed increase, however, it generally remains more or less below the preoperative level and, even if the preoperative level is reached, the symptoms of hypertension remain suppressed. The general condition of the patients is so greatly improved that some can resume their occupations. The renal function is improved and the degeneration of the secretory elements of the kidney is arrested, at least for a shorter or longer period.

Acetabular Protrusion Its Pathogenesis Costantini Bonnet and Brebant—p 1833

\*Hypophyseal Diabetes Action of Fever II Zondek and A Kaatz—p 1835

**Hypophyseal Diabetes Action of Fever**—Zondek and Kaatz describe two cases of hypophyseal diabetes. The first patient was a woman aged 32 who presented hypophyseal symptoms (endocrine obesity, psychic depression and manifest diabetes with constant increase in weight). The second patient was a man aged 30 who had a hypophyseal tumor and symptoms of hypophyseal dissociation (nanism, acromicria hypergenitalism, osteoporosis, delayed ossification of the growth cartilages and symptoms of hypothyroidism with mental and physical infantilism) complicated by latent diabetes. In both cases the diabetes was cured after an attack of fever, in the woman after an attack of angina and in the man after a fever that was provoked by the intravenous injection of antityphoid vaccine. In both cases the diabetes was of the hypophyseal type, the fever must have inhibited a diabetogenic principle. Whereas fever produces ordinarily an aggravation of pancreatic diabetes, it can have the reverse effect in certain cases of hypophyseal diabetes. The authors discuss the interglandular relations that are involved in the metabolism of carbohydrates. They are inclined to believe that the principle inhibited by the fever is not the diabetogenic hormone described by Houssey but rather that which acts through the medium of the adrenal cortex (according to the opinion of Long). The diabetes results in these cases in an exaggerated transformation of nonhydrocarbonaceous substances into carbohydrates in accordance with von Noorden's theory of diabetes, but it is possible that outside of this factor there are still others that intervene, factors which inhibit either the fixation of glycogen or the oxidation of sugar. Thus the modern ideas of the nature of diabetes approach more and more the conception that it represents a complex disturbance of the interglandular regulation, as is the case in other endocrine disorders, exophthalmic goiter for example.

\*Zambrini's Ptyaloreaction in Surgical Diseases C Rendano—p 537  
Varices of Jugular Vein Case P Giliberti—p 551  
Congenital Partial Macrosomia Case F Iovino—p 560  
Bacteremia in Tetanus L Sanguigno—p 567

**Zambrini's Ptyaloreaction in Surgery**—Zambrini's reaction on saliva for the diagnosis and prognosis of vital resistance, its technic and several of its applications have been described in various medical journals, especially French and Italian, and in THE JOURNAL, Nov 14, 1936, page 1679, and April 2, 1938, page 1150. The test is based on the changes of saliva produced by the addition of a coloring reagent and measured by a standard colorimetric scale with figures from 16 to 1, which represent a scale of dark to light shades which stand respectively for good vital and for poor organic resistance. Aside from the color of the saliva reagent mixture the possible presence of turbidity, sediment and a yellow crescent

figure on the surface of the mixture are studied. In normal individuals the mixture is limpid and without the presence of either sediment or the crescent figure. The phenomena of turbidity and formation of sediment in the mixture follow in all cases the behavior of the colorimetric curve. Rendano followed the behavior of the test in more than 100 persons with surgical diseases who were to be operated on. The author found that there is an obvious agreement between the results of the test and the general conditions of the patients before the operation and in the course of the postoperative period. The prognosis for an operation is excellent if the curve of the colorimetric test shows figures within 16 and 13, good for figures within 12 and 9, reserved under 8 and unfavorable under 5. After the operation the colorimetric curve descends. If the evolution of the postoperative period is normal the colorimetric curve rises uninterruptedly from the second day on, oscillates within high figures and rapidly becomes normal. The development of local or general complications is preceded in one or two days by a lowering of the colorimetric curve, which remains within low figures for as long as complications threaten or develop. The curve rapidly regains either normal figures or figures which existed before the operation if complications are controlled. The curve drops abruptly in cases of infected operation wounds with suppuration. The curve rapidly returns to normal after complete elimination of pus and control of the infection. The author believes that the test is of value in estimating the organic resistance and powers of defense of the patient in relation to immediate results of an operation. It is also of value in showing the development of complications in the course of the postoperative period early enough to make it possible to control them by early treatment.

\*Triphasic Complex in Lead 3 of Electrocardiogram D Gross—p 2331  
Parathyroids Clinical and Biologic Study P Rojas and F J Manfredi—p 2335  
Achylic Hypochromic Anemia Differential Diagnosis E S Marzetti—p 2339

**Triphasic Complex in Lead 3 Electrocardiograms**—Gross made electrocardiographic studies of 250 of his patients who had heart disease. The electrocardiograms in lead 3 of twenty-five of the patients (nineteen men and six women) showed a triphasic complex (biphasic S wave). All the patients complained of precordial pain of the anginous type or of a dull pain of light intensity and uncertain precordial location. Most of the patients were close to the age of 50. Sixteen presented organic disease of the heart. The arterial pressure was normal in sixteen and increased in seven. The electrocardiograms of fourteen were normal except for the presence of a biphasic S wave in lead 3. The altitude of the wave varied from 2 to 12 mm. The wave had an increased amplitude in fourteen cases. In all cases the abnormality of the S wave in lead 3 was independent of the behavior of the other waves in the electrocardiogram, whether normal or pathologic. According to the author the triphasic complex in lead 3 of the electrocardiogram is not caused by electrical preponderance of the left side. It represents metabolic disturbances of the myocardium which originate both in vascular alterations (coronary sclerosis) and in the action of various factors (toxic, humoral, metabolic and hormonal) on the myocardium. The clinical significance of the complex can be evaluated by the following criteria: 1 The presence of a triphasic complex in normal electrocardiograms in lead 3 in patients who do not show clinical symptoms of heart disease but who have a dull precordial pain is to be considered as a warning of pathologic changes of the heart. 2 The presence of a triphasic complex in normal electrocardiograms in lead 3 in patients who do not have clinical symptoms of heart disease but who have anginal precordial pain, or in pathologic electrocardiograms of patients who show clinical symptoms of heart disease whether or not there is anginal precordial pain, is a sign of diagnostic value for heart disease.

Diagnosis and Estimation of Traumatic Impairment of Patellar Cartilage G von Haberler—p 258

**Pneumatic Tools as Cause of Diseases of Muscles, Bones and Joints**—Schramm points out that heretofore disabilities caused by pneumatic tools have been reported chiefly in men who work in mines and in the stone industry but not so much in the men who use such tools in the iron and steel industry. In this paper he describes his observations on fifty-eight iron and steel workers who operated pneumatic hammers and riveters. The pneumatic tools used by these workers are not as heavy as those used in mines and quarries, and the riveters used their pneumatic tools only for about six or seven tenths of their working hours. The author gives a tabular report of his observations on the fifty-eight workers. The table lists the ages, the length of time the workers had used the pneumatic tools, disorders of bones and joints observed before the time the work with the pneumatic tool was begun, articular and osseous symptoms that appeared afterward, positive or negative roentgenologic aspects and complaints about vasomotor disturbances. He discusses some of the complaints and reproduces several roentgenograms. He points out further that if it is considered that of fifty-eight men fourteen had worked with the pneumatic tools less than two years and therefore could as yet not have developed changes and that ten were not subjected to roentgenoscopy (on account of previous injuries), it can be said that defects caused by pneumatic tools are not less in workers of the iron and steel industry than in mine and quarry workers. In this respect the author's observations correspond with those of the few others who made similar studies. The author detected typical changes on the elbow joint in three workers, on the shoulder joint in two and necrosis of the semilunar bone in one. That predisposition plays a part as well as exposure is proved by the fact that some workers who had used the pneumatic tools for twenty-five years were free from complaints, whereas in a young worker, defects were noticeable after three years. Discussing the prevention, the author stresses the importance of selecting the right type of tool in accordance with the hardness of the material to be worked on. He also recommends the use of devices to reduce the effect of the recoil of the tools. Moreover, the exhaust opening for the escape of the compressed air should be adjustable so that the cold blast hits neither the guiding hand nor the body of the worker. The men who work with pneumatic tools should be subjected to examinations at regular intervals in order that possible impairment may be recognized early.

**Action of Active Principle of Anterior Lobe of Hypophysis After Splenectomy**—Rarei and Gummel investigated the content of gonadotropic substance in the urine of splenectomized animals and of patients who had undergone splenectomy. In order to be able to compare their results with those of Sauerbruch and Knake, they employed the same quantitative method as did those authors. Castration is also

followed by an increased elimination of gonadotropic substance in the urine but, since the peak of elimination is not reached until three or four months has elapsed since the castration, the authors gave especial attention to the time which elapsed after splenectomy before the increased content became evident. They found that during the first three months following the extirpation of the spleen the test for the follicle stimulating factor in the urine always produced negative results. The same was the case in splenectomized rabbits. However, in patients who had undergone splenectomy at least four months previously from 70 to 100 mouse units of the follicle stimulating factor was detected regularly in each liter of urine. These results correspond with those obtained by Sauerbruch and Knake, for these investigators detected on the average 50 mouse units of the follicle stimulating factor per liter of urine in cases in which one year or more had elapsed since splenectomy. In further investigations Rarei and Gummel aimed to determine whether the anterior lobe of the hypophysis of splenectomized animals forms more gonadotropic substance. They implanted the hypophyses of splenectomized rats into young female rats, pointing out that from four to six normal rat hypophyses are required for a positive Aschheim-Zondek reaction in such animals. In performing this experiment they found that the hypophyses of splenectomized rats were not heavier than the hypophyses of normal controls of the same age and weight. The implantation of the hypophyses of these splenectomized rats into young rats was not followed by an increased formation of gonadotropic substance, that is, hypophyses of splenectomized rats had about the same effect on the ripening of the follicle as did the hypophyses of normal animals. The authors conclude that their results seem to indicate that the increased elimination of gonadotropic substance can be given a similar interpretation as that which develops after castration, however, the theory that the spleen intercepts and destroys the gonadotropic substance cannot be accepted, because in newly splenectomized patients and animals the test is always negative. To be sure, although they obtained results similar to those reported by Sauerbruch and Knake, they do not feel justified in asserting definitely that splenectomy acts on the gonadotropic exchange similar to castration, because the knowledge about the formation of gonadotropic substance under normal conditions is as yet too limited and the patients who had undergone splenectomy were subject to such serious systemic diseases (leukopenia, thrombopenia, splenic tumors and so on) that their hormone regulation cannot be compared with that of healthy persons.

- \*Massive Atelectasis and Bronchiectasis as Complication of Primary Pulmonary Tuberculosis in Children J Zeyland—p 209  
Distribution of Tuberculous Infection in Finnland S Savonen—p 219  
Pulmonary Tuberculosis As Late Complication After Wound of Lung H Rieckenberg—p 226

**Atelectasis and Bronchiectasis Complicating Tuberculosis in Children**—According to Zeyland, credit for having called attention to massive atelectasis as a complication of pulmonary tuberculosis is due chiefly to American authors. Before describing five typical cases that he observed, Zeyland says that the development of massive atelectasis (of an entire lung or an entire pulmonary lobe) may take place unnoticed if it is gradual, but that in case of sudden development the symptomatology may be like that of pneumonia. Atelectasis of large portions of the lung is accompanied by impairment of the respiratory excursions, retraction of the thorax on the diseased side, elevation of the diaphragm of the same side shifting of the mediastinum toward the same side, reduced percussion sound weakening or abolition of the respiratory sounds on the diseased side occasionally tracheal or bronchial breathing in the upper field as the result of distortion of the trachea and sometimes also at the base of the atelectatic lobe, even in the absence of bronchiectasis. In partial atelectasis there may also be rales. The author thinks that many cases of so called splenopneumonia are in reality unrecognized cases of atelectasis. Stressing the greater reliability of roentgenologic examination in the demonstration of the symptoms of atelectasis,

he gives especial attention to the pendular movements of the mediastinum, that is, during inspiration the mediastinum deviates toward the diseased side because it is pushed aside by the healthy lung. This pendular movement of the mediastinum is important in the differentiation of atelectasis from pulmonary cirrhosis and pleural adhesions, since all other symptoms may be the same in these different conditions. Atelectasis is a reversible process but may give rise to an entirely new disease entity, namely pulmonary cirrhosis (pulmonary fibrosis), which is irreversible. The development of pulmonary fibrosis is accompanied by the development of bronchiectasis. Bronchography is important for the diagnosis of bronchiectasis. The anamnesis and clinical observation furnish only pointers, bronchography is necessary to make the diagnosis definite, especially in children with a positive tuberculin reaction. This is evident in the cases the clinical histories of which are described in this report. In the first case a massive atelectasis of the upper left pulmonary lobe was caused by a temporary enlargement of the tracheobronchial lymph nodes and by their pressure on the bronchus. The complication in the form of the atelectasis disappeared completely, and after that roentgenoscopy revealed only the calcified primary complex in the left lung. In such cases it is important to differentiate between atelectasis and epituberculous pulmonary infiltration. In the second case an atelectasis of the left lung developed in connection with a primary pulmonary tuberculosis, probably as the result of pressure by an enlarged lymph node on the left bronchus, which was contracted and bent. The chronic atelectasis developed into partial pulmonary fibrosis with bronchiectasis. The third case resembled the second one, but the bronchiectases were more pronounced. In the fourth case the atelectasis evolved on the basis of a tuberculous process and it developed into a pulmonary fibrosis. The fifth patient presented the typical aspects of an atelectasis of the upper lobe, which was most likely connected with the tuberculous infection.

**A Total Thoracoplasty with Resection of the Lower Ribs**—While approving of the operation of partial thoracoplasty in some cases, Gilman stresses its disadvantages, such as aspiration of the tuberculous processes by the lower pulmonary segment and above all the deformities to which it predisposes. On the other hand, scoliosis is practically unknown after a total thoracoplasty. The deformities are particularly prone to develop in patients of asthenic habitus and thoracic asthenic bodily conformation. Furthermore, partial thoracoplasties are successful only in the presence of small cavities located in the periphery of the lung. While admitting the desirability of preserving the maximum amount of pulmonary tissue, the author feels that it is wiser in the majority of the cases to sacrifice pulmonary tissue in order to obtain an adequate collapse. For patients with asthenic type of chest the author recommends a total thoracoplasty with what he calls "economic" resection of the lower ribs. The operation consists of the usual upper thoracoplasty or of complete removal of the first two or three ribs. This is either preceded or followed by an "economic," that is, partial, resection of the lower four or five ribs. This operation results in an even, more physiologic narrowing of the thoracic cage and a more rapid return to the physiologic balance. Partial resection of the lower ribs interferes but little with the respiratory function of the lower segment of the lungs. This modification of a total thoracoplasty is recommended by the author for asthenic patients, for enfeebled patients requiring an extensive upper plastic operation, for patients with fresh lesions and for patients with extremely large cavities.

**X-Ray Diagnosis of Intestinal Obstruction**—Høyer points out that it may be difficult to make the clinical diagnosis of intestinal obstruction in the first twenty-four hours because of the fact that the symptoms typical of this lesion may be totally or partly absent. The pain generally gives rather indefinite data on which to base the diagnosis, as it is indistinguishable from colicky pain of other causes and it has no typical location. Neither does the vomit supply information before the vomitus becomes foul. This is a late symptom, however, and indicates that the situation is becoming exceedingly grave. Information to the effect that there has been no passage of feces or flatus is of small value during the first twenty-four hours. The signs also are scarce during the first twenty-four hours. In view of these difficulties encountered by the clinical diagnosis it was of great importance that Kloiber in 1919 discovered that the x-ray diagnosis of intestinal obstruction could be made with great certainty at an early point of time, without contrast mediums, only by x-ray examination with horizontal direction of the rays. In this manner he revealed the characteristic fluid levels caused by the simultaneous presence in the intestine of gas and thin intestinal contents. After reviewing Kloiber's experience with roentgenoscopy in 100 cases showing acute abdominal symptoms, the author describes and illustrates the x-ray symptoms of intestinal obstruction. When an occlusion takes place, the immediate result is an accumulation of thin intestinal contents in the oral direction, whereas anally to the occlusion the intestine is more or less completely emptied. There is increased peristalsis. The intestine makes every effort to pass the obstruction. Not infrequently patients with obstruction of the small intestine have spontaneous defecation shortly after the onset of the pain. Next comes an abnormal fermentative process of the intestinal contents with development of gas. This supplies conditions for the formation of fluid levels which, according to Kloiber, commences two or three hours after the onset of the attack. In mechanical ileus the fluid levels are usually visualized in two segments of the same coil at different heights. Fluoroscopic examination may demonstrate how the fluid levels rise and fall. This symptom is an important aid in the differential diagnosis between mechanical and paralytic ileus. In paralytic ileus the peristalsis has ceased and the fluid levels are stagnant. The coil of intestine lying immediately proximal to the obstruction, the so called prestentotic coil, frequently presents a peculiar condition. The peristalsis here is particularly strong. The coil rises in the abdomen in the form of a reversed U. It has a stiff appearance. The tonus seems to be stronger than in the other dilated intestines. If an entire coil of the small intestine is shut off from the intestinal tract, both segments being strangulated, this coil becomes greatly dilated by gas and is easily recognizable in the roentgenogram. At the same time this supplies the accurate topical diagnosis, which is represented clinically by the "hypogastric football" (Wahl balloon symptom). The author further mentions a roentgenologic symptom which, in his opinion, is of great importance to the diagnosis. This is the more or less complete absence of gas from the large intestine in the presence of obstruction of the small intestine. The author says that at the surgical department of his hospital x-ray examination is now employed in all cases of suspected intestinal obstruction. The material available so far includes forty-six cases. In all cases the x-ray examination supplied a correct reply as to whether or not an intestinal obstruction was present. In a majority of cases the site of the lesion could be given. The mortality from intestinal obstruction has decreased considerably subsequent to the adoption as a routine method of the x-ray examination of abdominal cases in which intestinal obstruction is suspected.

## A STUDY OF PELVIC TYPE

AND ITS RELATIONSHIP TO BODY BUILD IN  
WHITE WOMEN

WILLIAM WALTER GREULICH, PH D

AND

HERBERT THOMS, M D

WITH THE COLLABORATION OF

RUTH CHRISTIAN TWADDLE, B N

NEW HAVEN, CONN

In the literature of both anthropology and obstetrics, the pelvis of the white woman is described as having an inlet the transverse diameter of which is considerably larger than the anteroposterior, or conjugate, diameter. The pelvic index, i. e. the ratio of the anteroposterior to the transverse diameter of the inlet  $\times 100$ , is said to be less than 90 in white women, who are, accordingly, classed as platypellic. Pelves with a relatively larger anteroposterior diameter and with a pelvic index ranging from 90 to 94.9 are classed as the mesatipellic type. Those with an index of 95 or more, the dolichopellic type, are supposed to be characteristic of what are frequently referred to as the "more primitive" races. Thus, according to data compiled by Martin,<sup>1</sup> Negroes, Melanesians and Tasmanians are mesatipellic, while Bushwomen, Hottentots, Australians and Malays are dolichopellic.

In a paper by Dr Hans Scheyer<sup>2</sup> on the pelvis of the Chinese woman, there is a discussion of the relative primitiveness of the various types of pelves which seems to reflect rather accurately the opinion held by many anthropologists and others on this point. He writes:

From observations on the orang-outan it is known that the man like apes as well as all of the mammals have so called long oval pelves wherein the long axis is antero-posterior. The aborigines also have this long oval pelvis. So Fritsch found the stunted pelvis with the long oval entrance among the Hottentot and Bushwomen. With the evolution of the races one finds a tendency in the development of the pelvis from the long oval through the round to the transverse oval. Among European women generally the pelvis is transverse oval in shape. If a long oval pelvis is found it is considered pathological. Likewise the round pelvis when found in European women is a sign of underdevelopment (infantilism).

From the Departments of Anatomy, Obstetrics and Gynecology and the Adolescence Study Unit, Yale University School of Medicine.

This investigation was aided by grants from the Fluid Research Fund of Yale University School of Medicine and from the General Education Board of the Rockefeller Foundation.

Dr. Hugh M. Wilson, associate professor of radiology at the Yale School of Medicine, kindly made available to us the necessary radiologic facilities for this study. Mr. Laurence E. Cowles, technician in radiology, made the pelvic roentgenograms, and Mrs. C. B. Bidwell, Miss Esther Setlow, and Mr. R. L. Kemler of the Adolescence Study Unit did most of the work of recording, tabulating and charting our data.

## INCIDENCE OF THE VARIOUS PELVIC TYPES

Practically all published descriptions of the dimensions and configuration of the pelvic inlet are based on measurements made on cadavers or on dried pelves. With the development of satisfactory methods of roentgen pelvimetry, however, it has become possible to measure the pelvic inlet of living women with a rather high degree of accuracy. We wish to report these dimensions as determined by Thoms's method of roentgen pelvimetry<sup>3</sup> in 582 primigravid white women from the Obstetrical Clinic of the New Haven Hospital, 104 nulliparous young white women, most of whom were students of the Yale School of Nursing, and 107 young girls who ranged in age from 5 to 15 years.

In table 1 are listed the percentages of the different types of pelves found in this series of 793 white females. It will be noted that 73 per cent of the student nurses, 37.3 per cent of the clinic patients and 82.2 per cent of the young girls were dolichopellic, that 13.5 per cent of the student nurses, 27.5 per cent of the clinic patients and 9.3 per cent of the children were mesatipellic and that only 13.5 per cent of the student nurses, 35.2 per cent of the clinic patients and 8.4 per cent of the children were platypellic. Thus, of the 686 adult women studied, 68.1 per cent had a pelvic index of 90 or more and were therefore either dolichopellic or mesatipellic. The platypellic type, which is usually regarded as proper for white women, was found in only 31.9 per cent of the adults in our series. The high incidence of dolichopellic and of mesatipellic pelves among the adult white women of our series and the much lower incidence of the type usually considered to be characteristic of this race suggest that the prevailing concept of the latter is in need of some revision.

Special interest attaches to the high percentage of dolichopellic pelves among the student nurses for, on the basis of their pelvic type, 73 per cent of them showed a rather embarrassing resemblance to Hottentots and Bushwomen. This is especially surprising in view of the relatively high economic level and the superior physical status of the young women of whom that group was composed. More than two thirds of them were college graduates and a considerable percentage of the latter were alumnae of Mount Holyoke, Smith, Wellesley, Radcliffe or Vassar. As a group they gave the impression of having attained something at least approximating their maximum normal growth potentialities.

Despite the high incidence of round and of long oval pelves among the student nurses there was no indication of anything pathologic about them and, as may be seen from the accompanying illustrations, they were most

<sup>3</sup> Thoms, Herbert. *Roentgen Pelvimetry*. Radiology 21: 125 (Aug.) 1933. Thoms, Herbert and Wilson, H. M. *Roentgen Methods for Routine Obstetrical Pelvimetry*. Yale J. Biol. & Med. 10: 437 (May) 1938.

There is some further evidence that seems pertinent in this connection. In 1923 Thoms and Hershman<sup>10</sup> described a case of precocious puberty in a girl who menstruated first at the age of 3 years 7 months and whose menstrual periods continued with ordinary regularity up to within about one year of her death, which

There remains, of course, the possibility that the hormonal and associated factors elicited an atypical response from the developing pelvis in this girl because of the abnormally early period at which they began to operate. The fact that the mammary glands, the uterine mucosa, the subcutaneous fat and the axillary and pubic hair follicles all responded in a normal manner to these hormonal influences does not however, support such an assumption. It will be noted that the pelvic inlet

Fig 4—There is a range of 167 cm in the stature of these five women and there are comparable differences in their other dimensions. Note the variation in the shape of the inlet despite the fact that the anteroposterior and maximum transverse diameters are the same in all cases. The pelvic inlet of the shortest woman in this group (the third) appears to have the greatest area. The shape of the pelvic inlets of the first and second women is very similar despite a marked difference in all external dimensions except the external conjugate diameter. The tracings of the fourth and fifth women show some flattening of the forepart of the inlet. In both of them the promontory of the sacrum projects slightly into the superior strait.

#### PHYSICAL MEASUREMENTS

Conjugate diameter	11 50	11 50	11 50	11 50	11 50
Transverse diameter	12 70	12 70	12 70	12 70	12 70

occurred at the age of 18½ years, following an operation. Figure 1 shows the child at the age of 4 years and at 8 years and 4 months. It will be noted that, at the time the second picture was taken, she appeared to be physically mature, the breasts and the pubic hair were essentially adult in type and the amount and distribution of subcutaneous fat had imparted to the body a contour which resembled that of a normal woman. In this illustration is reproduced a pelvic roentgenogram of this child made when she was 11 years of age. As is usual in such cases, her skeletal development was advanced far beyond that proper to her chronological age. Though they are not visible in the accompanying illustration, the centers for the crests of the iliums were already present, and the fusion between each ilium, ischium and pubis had proceeded to a point at which it was no longer possible to distinguish the line of their junction in the roentgenogram. Her pelvic inlet at that time was long oval. As determined by Thoms's method of roentgen pelvimetry about seven years later, the dimensions of the inlet were found to be 12 cm anteroposterior and 11.3 cm transverse.

This is an instance in which the bony pelvis was subjected to the influence of the female sex hormones during its entire formative period. The end result was a pelvis the inlet of which was elongated anteroposteriorly.

<sup>10</sup> Thoms, Herbert and Hershman, A. A. A Case of Sexual Precocity. *Am J Obst & Gynec* 6: 349 (Sept.) 1923.

TABLE 4—Incidence of Operative Intervention

Type	Number	Per Cent

Outlet forceps	76	

of this girl resembles very closely the type most frequently observed among the student nurses of our series.

#### A COMPARISON OF BODY BUILD AND PELVIC TYPE

It is self evident that, if a mammalian species is to survive, the pelves of the females of that species must be large enough to permit the birth of their young. It was a recognition of the necessity of such a relationship which led anthropologists of the nineteenth century to

Fig 5—The pelvic tracings of these three women are very similar though there is a slight asymmetry of the forepart of the inlet of the first woman. The second woman shows in addition to her greater height strikingly broader shoulders, a narrower waist and broader hips in proportion of her bicristal diameter than the other two women.

#### PHYSICAL MEASUREMENTS

Conjugate diameter	12 50	12 50	12 50
Transverse diameter	12 75	12 75	12 75
Standing height	167 1	179 0	179 0
Sitting height/standing height	49 8	51 0	51 0
Cephalic index	79 3	61 2	78 9
Biacromial	30 6	36 9	35 3
Bicristal	31 1	29 1	26 8
Bitrochanteric	32 8	33 6	32 8
External conjugate	19 7	21 9	20 3

expect a rather close correspondence between the shape of the head and the shape of the pelvic inlet in various races. There persists today a somewhat similar notion, implicit in the opinion of many obstetricians, that a rather closer relationship exists between pelvic type and body build. It is said, for example, that short, stocky women tend to have a relatively wide pelvic inlet, whereas tall, linear women are more likely to have the round or the "anthropoid" type. It seemed desirable to investigate this possible relationship and especially to determine whether there are any external characters which would serve to distinguish women of one pelvic type from another. We accordingly measured and photographed 132 of the clinic women and the 104 student nurses of our series and compared the various average dimensions of the women of the different pelvic

height, however, did not differ significantly from one pelvic type to another, among either the student nurses or the clinic women.

3 The average cephalic index was lowest among the dolichopellic, somewhat higher among the mesatipellic and highest among the brachypellic women of both groups. Thus, long oval pelvis occurred most frequently among women with relatively long, narrow heads, whereas round and transversely elongated pelvis were most frequently associated with relatively broader heads. There was no comparable correspondence between pelvic type and facial index.

4 The average biacromial breadth of the student nurses was larger than that of the clinic women in every pelvic type. In both groups of women this dimension was largest among those having long oval or round

TABLE 5—Average Physical Measurements of 132 Clinic Women and 104 Student Nurses Grouped According to Their Pelvic Type\*

	Pelvic Type					
	Clinic Women				Student Nurses	
	Dolichopellic	Mesatipellic	Brachypellic	Platypellic	Dolichopellic	Mesatipellic
Number of cases	18	58	51	5	39	46

Average biacromial width	34.8	34.6	33.9	34.1	35.9	35.6
Range	32.5-36.7	31.2-35.6	31.0-37.5	30.5-36.0	32.3-39.0	31.6-38.5
Average bicristal width	27.6	27.7	27.5	27.5	28.7	28.6
Range	22.1-30.9	24.9-32.5	25.1-30.3	23.8-31.0	25.2-32.0	26.0-32.3
Average bitrochanteric width	33.3	33.3	33.4	32.6	33.1	32.8
Range	30.2-39.4	30.0-38.8	29.0-38.5	29.4-36.7	29.3-36.3	30.4-35.8
Bicristal / biacromial	79.3	79.6	81.2	80.6	79.9	80.6
Bitrochanteric / biacromial	95.7	95.7	98.3	97.1	90.8	92.0
Average external conjugate diameter	19.8	19.3	18.6	18.4	19.8	19.7
Range	17.5-21.0	17.0-22.0	16.5-27.0	17.0-20.0	16.9-22.9	16.4-23.1
Dimensions of pelvic inlet						
Average anteroposterior diameter	11.8	11.8	10.7	9.9	12.9	12.0
Average maximum transverse diameter	12.1	12.4	10.8	13.2	11.6	12.4

\* The data have been checked statistically by Dr. Frank Shuttleworth of the Yale University Institute of Human Relations. The correlation between the bicristal diameter and the maximum transverse diameter of the pelvic inlet was only 0.40, and that between the external conjugate and the anteroposterior diameter of the inlet was 0.41. These were the highest correlations noted. They confirm the observed unreliability of external measurements in predicting the dimensions of the inlet.

types. The measurements so obtained are listed separately for the clinic women and for the student nurses in table 5. The average measurements of the five platypellic clinic women have been included in the table, for the sake of completeness, even though the number of such cases is too small to permit a valid comparison of their measurements with those of the other pelvic types. They have, however, been omitted in the subsequent discussion. It will be noted that in some instances the platypellic group did, and in others they did not, conform to the trends here outlined.

Attention is directed to the following relationships between pelvic type and body build, which seem to be indicated by our observations.

1 The clinic women and the student nurses who had long oval (dolichopellic) or round (mesatipellic) pelvis were, on the average, the tallest women of our series, those with a relatively wider pelvic inlet, the brachypellic type, were the shortest. The student nurses were taller than the clinic women of the corresponding pelvic type.

2 The clinic women had relatively longer trunks and shorter legs than the student nurses of corresponding pelvic type. The ratio of sitting height to standing

pelvis and smallest among those having transversely elongated pelvis.

5 There was no significant difference in average bicristal diameter between the various pelvic types among either group of women. The average bicristal diameter of the student nurses was, however, greater than that of the clinic women of corresponding pelvic type.

6 As shown by the ratio of their bicristal to their biacromial diameters, the shoulders of the student nurses of each pelvic type were wider in proportion to the width between their iliac crests than were those of the clinic women. In both groups, however, this excess of the biacromial over the bicristal diameter was largest among the women with long oval pelvis, somewhat smaller among those with round pelvis and smallest among those with transversely elongated pelvis.

7 The average bitrochanteric breadth was larger among the clinic women than among the student nurses in each pelvic type. This dimension was not significantly larger in women with transversely elongated pelvis than it was in those with the round or long oval type.

8 The ratio of the bitrochanteric to the biacromial diameter was higher among the clinic women than among the student nurses of corresponding pelvic type. In both groups this ratio was higher in the brachy-

Fig. 6—Though their pelvic tracings are very much alike these three women are quite different in their external dimensions and general bodily configurations

#### PHYSICAL MEASUREMENTS

Conjugate diameter	13.0	13.0	13.0
Transverse diameter	12.5	12.5	12.5
Standing height	170.1	159.2	173.0
Sitting height/standing height	51.8	53.4	51.8
Cephalic index	72.1	81.5	81.4
Biacromial	30.0	31.1	38.1
Bicristal	27.4	29.2	30.1
Bitrochanteric	32.7	32.4	35.0
External conjugate	19.8	19.0	21.8

pelvic than in the mesatipellic or dolichopellic women. The width of the hips across the trochanters, in women with transversely elongated pelves, was therefore greater in proportion to the width of their shoulders than in women with round or long oval pelves.

9 The average depth of the chest at the level of the fourth costosternal articulation (mesosternale) was found to be greater among the clinic women than among the student nurses, but there appeared to be no consistent relationship between that dimension and the pelvic type.

10 The average external conjugate diameter was found to grow progressively smaller as one proceeded from the long oval to the round and finally to the transversely elongated pelves. There was, however, considerable variation in this dimension between women of the same pelvic type and even between some in whom the true conjugate diameters were identical.

These results may be summarized as follows (a) The women with long oval pelves (dolichopellic) were predominantly tall, long headed and broad shouldered. The width of their pelves between the iliac crests and of their hips between the trochanters was smaller in proportion to the width of their shoulders than in women of the other pelvic types, and they had the largest average external conjugate diameter. (b) The women with transversely elongated pelves (brachypellic) were, on the average, the shortest of the series,

and they had the broadest heads, the narrowest shoulders, the widest pelves and hips in proportion to the width of their shoulders, and the smallest average external conjugate diameter. (c) The women with round pelves (mesatipellic) were approximately intermediate between the other two groups in all these dimensions.

TABLE 6—Nationality of the Women Examined

Country of Origin	Clinic Women	Student Nurses
England	4.9%	41.8%
Scotland	0.8%	10.3%

\* Subsequent inquiry disclosed that these student nurses were of Northern European ancestry.

It should be emphasized that the characters just enumerated are based on average dimensions of groups and that the characters which distinguished one group were not possessed to the same degree by every member of that group. As indicated by the range of the various measurements listed in the table there was con-

Fig. 7—Though the shape of these three pelvic tracings shows minor differences they are all characterized by the same degree of anteroposterior flattening. The three women however are very different. The shape of the inlet of the second woman corresponds very closely to that pictured in the last edition of Gray's Anatomy as a typical female pelvis although the woman herself has anything but a typical feminine figure.

#### PHYSICAL MEASUREMENTS

Conjugate diameter	10.5	10.5	10.5

External conjugate	16.2	19.0	20.5

siderable overlapping from one pelvic type to another in practically all these measurements. Indeed, this variation was so great that we were unable to find any measurement or index or any combination of measurements or of indexes from which the pelvic type might safely be predicted in individual cases. In this connection attention is directed to the fact that in some average measurements and indexes there was a greater difference between clinic women and student nurses of the same pelvic type than there was between different pelvic types within either the student or the clinic group.

The observed differences in average bodily dimensions between the clinic women and the student nurses are, in part, attributable to the different racial composition of those two groups. In table 6 are listed the countries of origin of the ancestors of 119 of the 132 clinic women and of ninety-two of the 104 student nurses. One or both parents of eighty-five, or 71.4 per cent, of the clinic women and of eighteen, or 19.5 per cent, of the student nurses from whom this information was obtained were foreign born. Though the majority of the student nurses were descended from two or more generations of American-born ancestors, the countries from which the latter originally emigrated are also listed in table 6 in order that the racial composition of the two groups may be compared.

It will be noted that 63.9 per cent of the student nurses were of English, Irish, Scottish or Welsh descent, as compared with 11.5 per cent of the clinic women. Of the clinic women 29.4 per cent were of Italian and 18.3 per cent were of Polish, Lithuanian or Russian parentage, whereas there were no Italians among the student nurses and only 9.1 per cent of them were of Polish, Lithuanian or Russian parentage. Judging from the appearance of the clinic women whose parents were listed in their case history as having been born in the United States, the majority of them also were Italian or Slavic in origin. It is apparent from the table that the student nurses were predominantly of North European stock whereas the clinic women were mostly of Italian or Slavic origin.

It is because the clinic women and the student nurses differed so much in racial composition and in economic level that we have listed separately their average physical measurements and the incidence of the various pelvic types among them. As has already been pointed out, the student nurses, who were predominantly dolichopelvic and mesatipellic, were on the average larger than the clinic women of the corresponding pelvic type in practically every bodily dimension. It is interesting to note that among both the clinic women and the student nurses the women who had long oval (dolichopelvic) or round (mesatipellic) pelvises were the largest of their respective groups. The greater average size of the dolichopelvic and the mesatipellic women in these two racially and economically diverse groups, together with the evidence we have presented for the functional adequacy of these two types of pelvises during parturition, does not support the assertion that such pelvises are indicative either of infantilism or of some pathologic state when they occur in white women.

It seems reasonable to assume that if any reliable correspondence exists between pelvic type and body build it would be reflected in a similarity in external dimensions and in general bodily configuration of women who have pelvises of the same type and that such resemblance ought to be especially striking in women in whom the dimensions of the pelvic inlet are identical. In the accompanying illustrations we have accordingly

grouped together photographs, tracings of the pelvic inlet made from the x-ray films and the principal anthropometric measurements of women from our series in whom the dimensions of the pelvic inlet were found to be identical. The photographs and tracings are reproduced to scale and together with the measurements are arranged so as to facilitate comparison.<sup>11</sup>

Even a cursory examination of the illustrations will substantiate our conclusion that women in whom the size and shape of the pelvic inlet were identical can resemble one another very closely, only slightly or not at all in general appearance and in their other bodily dimensions. Figure 10 is especially instructive. The woman shown in the middle of the illustration has a pelvic inlet identical in dimensions with, and very

Fig. 8—Despite the similarity in the shape of the pelvic inlets of these three women they differ considerably in stature and to a somewhat less extent in their other bodily dimensions. Note especially the broad shoulders, narrow waist and relatively broad hips of the woman on the right.

#### PHYSICAL MEASUREMENTS

Conjugate diameter	12 7½	12 75	12 7½
Transverse diameter	13 0	13 0	13 0
Standing height	167 8	174 4	168 8

similar in outline to, that of the woman shown on her left, but they are very different in stature and in their other bodily dimensions. The woman on her right, however, resembles the central figure very closely in practically all her external measurements, but she has a pelvic inlet of a most contrasting type. It is also evident therefore, that women who are much alike in their other bodily dimensions and proportions can have pelvises which are very different from one another.

Throughout this paper we have described the pelvis in terms of the size and shape of the inlet, merely because it is that aspect of the pelvis that is stressed most in the textbook descriptions of the "normal" female pelvis. We do not, however, wish to seem to

11. For mechanical reasons figures 3 and 4 had to be reduced about one fourth from the scale of the others.

minimize the obstetric importance of other dimensions of the birth canal, we are quite aware of the existence of variations in those dimensions among pelvises with the same type of superior strait

#### SUMMARY AND CONCLUSIONS

1 The type of pelvis that is described in textbooks of anatomy and of obstetrics as the "normal" female pelvis was found in only 14.9 per cent of 582 primi-

Fig. 9—This illustrates the degree of variability that may be encountered in the shape of the inlet of pelvises which have the same anteroposterior and transverse diameters. The second, third and fourth tracings show progressive flattening of the forepart of the pelvis. In the fourth the sacral promontory projects somewhat into the superior strait. The differences in the dimensions and external configurations of these four women are however much greater than the differences in the shape of their pelvic inlets.

gravid white women from the obstetric clinic of the New Haven Hospital, 5.7 per cent of 104 student nurses who were of somewhat different racial stock and a much more privileged economic group than the clinic women, and 8.5 per cent of 107 young girls who ranged in age from 5 to 15 years. Only 31.9 per cent of the 686 adults of this series had the type of pelvis which, according to the anthropologic literature, is proper for white women.

2 Among 600 primiparous white women from the same clinic, the percentage of operative intervention required during delivery was lowest among those with long, oval pelvises, somewhat higher among those with round pelvises and highest among those with transversely elongated pelvises—the type usually regarded as normal. The latter was therefore neither the normal—in the sense of being the most frequently occurring type—nor the most adequate type, as gaged by the frequency of operative intervention required during delivery by the women possessing it.

3 A comparison of body build and pelvic type in 132 of the clinic women and the 104 student nurses

disclosed the following relationships: (a) The women with long oval pelvises were predominantly tall, long headed, and broad shouldered, the width of the pelvis between the iliac crests and of their hips between the trochanters were smaller in proportion to the width of their shoulders than in women of the other pelvic types, they had the largest average external conjugate diameter. (b) The women with transversely elongated pelvises were, on the average, the shortest of the series and they had the broadest heads, the narrowest shoulders, the widest pelvises and hips in proportion to the width of their shoulders and the smallest average external conjugate diameter. (c) The women with round pelvises were approximately intermediate between the other two groups in all these dimensions. There was, however, so much variation in these external dimensions between student nurses and clinic women of the same pelvic type that, in our opinion, it would be quite hazardous to attempt to predict pelvic type on the basis of these dimensions in individual cases in a population as heterogeneous as that of this country.

4 The high incidence of long oval and of round pelvises among the largest women of both groups suggests the possibility that nutritive and other factors which make for the attainment of maximum normal growth tend to prevent that degree of anteroposterior flattening of the pelvis which has come to be regarded as characteristically feminine.

5 A comparison of photographs, external measurements and pelvic tracings of 132 clinic women and 104 student nurses showed that some women who resembled one another very closely in size and in general body build had pelvises which were very dissimilar and that, conversely, women in whom the size and shape of the

Fig. 10—The size and shape of the pelvic tracings of the first and second women are very much alike though the women themselves are very different in their external dimensions. The second and third women however resemble each other very closely in stature and in other external measurements but they have pelvises of extremely different types.

#### PHYSICAL MEASUREMENTS

## HYPOGLYCEMIA AND CONVULSIVE THERAPY IN SCHIZOPHRENIA

### CLINICAL OBSERVATIONS AND RESULTS

HANS H. REESE, M.D.

MADISON, WIS.

When Kraepelin sifted out fundamental types of psychoses and classified dementia praecox from a nosologic standpoint into four subtypes with different arial reaction pictures, he undoubtedly did much to clarify psychiatry. When Kretschmer then added various somatic substrates of personality model groups to the psychobiologic conception another advance was made. When Freud's theoretical principles of psychoanalysis and his concepts of the personality unraveled limitless tangles of psychic attitudes or conflicts, he benefited certainly the lot of mankind. Adolf Meyer's researches in psychobiology and psychopathology combined with his didactic attitude toward the inseparable unity of matter and its functions integrated the incongruities of life, and Petersen explained the autonomic dualism of biochemical fluidity with responses in the psychic mentation swings and its disintegrative effect on matter by meteorologic conditions.

This introduction with high points of progress, suggests the tremendous activity in psychiatric workshops and attests the preparedness of psychiatrists as clinicians to investigate the epochal contributions of Sakel and von Meduna. The multitudinous publications on insulin and metrazol shock therapy are the common knowledge today of scientifically minded physicians. Therefore I shall not delve into the historical development,<sup>1</sup> I shall not reiterate the technic or the phasic clinical course of either method, and I shall not waste time with statements as to precautions, complications and termination procedures.

The presented material comprises patients with schizophrenia legally admitted to the two state hospitals of Wisconsin—Mendota State Hospital (Dr M. K. Green), 108 patients, and Winnebago State Hospital (Dr G. E. Seaman), sixty-five patients. These patients after complete clinical and laboratory examinations, received treatment in special wards prepared solely for the administration of shock therapy. They returned to their various residence wards on termination of the therapy. The patients did not have any attention, supervision or occupational recreation differ-

ent from the usual care given as a routine at state hospitals. Such an ordinary hospital regimen was adhered to with the objective of judging the efficacy of the insulin and metrazol treatment per se and avoiding the possible influence of contributory psychic factors on the patients during this special study.

Statistical studies of the literature on insulin with regard to the incidence of remissions of disease of less than one year's duration show variation between 50 and 85 per cent, whereas the optimum number of recoveries in an untreated group is assumed to be 30 per cent. The duration of illness over one and two years reduces the percentage of remissions to 27 and 10 per cent respectively but it must be remembered that spontaneous remission in these groups is less common and occurs only after many months of hospitalization. Malzberg's<sup>2</sup> pooled statistics (New York civil state hospitals) gave for 1,035 untreated patients an incidence of recovery of 22.1 per cent after from one to two years of hospitalization.

Insulin remissions are of good quality. The patients present a higher degree of emotional rapport, a better insight and an unusual stability.

The quantitative and qualitative objective investigation of prolonged insulin recoveries from schizophrenic psychoses must be left to the future. Pooling of data and checking of remissions will permit an analysis by qualified and psychologically skilled psychiatric centers which have at their disposal a specially trained staff.

A number of percentage reports in the literature appear too optimistic, but even they do not as yet justify hypercritical condemnation of Sakel's or von Meduna's treatment. The recorded variations in remissions, improvements and failures may be explained, in my opinion, by the selection of the material, by the deviations from the standard technic and, naturally by the manner of statistical compilation.

The genetic-dynamic conception of schizophrenia as a matter of abnormal genotypic reactions, which by underlying physiochemical and psychobiologic alterations crystallize into strong feelings of inadequacy and dissociated thought complexes, or the psychoanalytic evaluation of twists and incongruities in a personality with a schizoid coloring, permits today classification of types from incipient schizophrenia to full-fledged psychosis. Needless to say, the statistician reporting only on disintegrating reactions in a leptosome, i.e., probable parergastic reactions, will surpass with a miraculous percentage of "cures" the investigator who bases his results on clinical types of schizophrenic reactions, i.e., catatonic, hebephrenic and paranoid subdivisions. My patients presented schizophrenic illness with habit deterioration, affective features, submission reactions and negativism or agitation. They furnished the data for this report.

Statements on the duration of the psychosis are often erroneous, as they depend commonly on lay persons' intelligence and constellation, on the milieu or social status and on the employment or activity. Therefore too rigid lines of duration of illness should not be drawn, they should in no way influence the prognosis for insulin or metrazol therapy.

I have adopted a slightly altered form of Sakel's<sup>3</sup> regimen which seems to shorten the period of pre-

From the Wisconsin Psychiatric Institute, University of Wisconsin. Aid from the Wisconsin Alumni Research Foundation made this study possible.

Read before the Section on Nervous and Mental Diseases at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

2. Malzberg, B. Outcome of Insulin Therapy read before the Quarterly Conference of the New York State Department of Mental Hygiene, March 26, 1938.

3. Sakel, Manfred. Neue Behandlungsmethode der Schizophrenie. Vienna: Verlag Moritz Perles, 1935.

matous treatment. An initial dose of 60 units of insulin is given. The daily increase, from 10 to 30 units is more rapid than that used by most workers and depends on the patient's symptomatic reactions until the shock dose ranging between 70 and 240 units has been determined (ascending phase). From this point on constant variations are necessary to avoid "sensitivity" to insulin. In other words, reductions from the maximum dose (240 units at Mendota and 460 units at Winnebago) to a still effective wet shock producing minimum becomes a necessity (descending phase).

A convulsion is by no means of grave prognostic import in the clinical course of insulin therapy. It must be remembered that even an uncomplicated deep comatose wet shock is always potentially precarious. It should never be allowed to continue for more than from two and one-half to three hours, and the total period of hypoglycemia must not exceed six hours. The patient has to be kept warm, the air passages must be kept open and respiratory disturbances must be combated immediately by frequent postural changes. The

cases are of importance. No convulsive response but an attack like petit mal creates a fear complex with a sensation of impending death. Repeated failure to produce convulsions and amnesia develop reactions which soon result in objective aversion, opposition and refusal to accept this therapy. I do not enforce metrazol medication on agitated and combative persons, because the emotionally induced vascular tension will be dangerously raised in these persons. To avoid the objections and the psychic irritations in metrazol failures, I have adopted the recommendation of Georgi.<sup>5</sup> Insulin in shock-producing amounts is given, and after two hours of hypoglycemia the patient is given a convulsion with metrazol. The convulsive episode is set at the time when the blood sugar level is lowest and the prevalent alkalosis is at its peak. These factors lower the convulsive threshold, and with small amounts of metrazol good convulsions are produced. The convulsions terminate the patient's hypoglycemic state, and he is able to take sugar water. Nevertheless, I control the intake of dextrose in these cases to prevent late after-shock.

A brief statement will suffice to give my idea of the efficacy and of the preference between the two methods, which I have reached from clinical observations and from statistical analyses. In my opinion, all patients with schizophrenic psychoses (reactions) should be submitted to insulin therapy first. During the course one must decide whether interspersing with or a change to metrazol convulsions seems advisable. In stuporous, depressed or catatonic patients a drastic metabolic shake-up with metrazol appears necessary to effect a response more favorable to insulin shock therapy. When one method fails, a trial at least of the other should be made.

A comparison of positive therapeutic results demonstrates a definite advantage of insulin over metrazol in all groups, whereas the failures reveal almost equal percentages. Outstanding was the number of full remissions with insulin of illness of less than one year's duration, with a falling off of the results for disease of over two years' duration. The former group is naturally the one in which after from two and one half to three months, by any method of active therapy, a larger number of remissions would be expected. I am aware that the series is too small and that a division into clinical groups from a deductive therapeutic point of view is impossible. The results might be improved with additional readjustment therapeutics. Our results do not approach the favorable data given in the world literature.

Dussik and Sakel<sup>6</sup> of Austria reported full remission in 70 per cent and spontaneous remission in 88 per cent for disease of less than one-half year's duration. Mueller<sup>7</sup> of Switzerland reported an incidence of 57 per cent for full and spontaneous remissions in disease of less than one year's duration and of 27 per cent in disease of less than two years' duration. Kueppers<sup>8</sup> of Germany reported full remission in 39 per cent and improvement in 40 per cent for disease of less than one year's duration and of 14 and 37 per cent, respectively, for disease of less than two years'.

Variations in dose of insulin during a typical course of treatment. The dots indicate values for blood sugar at the termination of shock. The doses of insulin are to be read in the left hand column of the figures in units and the values for blood sugar are in the same column in milligrams per hundred cubic centimeters. It is to be noted that in this instance 160 units of insulin was required to produce the first deep shock. Sensitivity to insulin then developed quickly necessitating gradual reduction in the dose to 30 units. With the latter dose the depth of shock was not constant from day to day. It is evident that the extent of depression of the blood sugar is largely independent of the size of the dose of insulin. The gaps in treatment were due to intercurrent illness.

critical physiologic danger zone is reached from one and one-half to two hours after the injection of insulin, i.e., when hypoglycemic irritation phenomena of neurogenic origin develop.

Hydration or dehydration, alkalinization with sodium bicarbonate or acidosis with ammonium chloride, administration of oxygen by nasal catheter during the wet and comatose shock phase and atropine medication for the purpose of blocking the compensatory epinephrine mechanism have not influenced materially clinical symptoms or the phasic course of the insulin-induced hypoglycemia.

Von Meduna's<sup>4</sup> metrazol treatment means artificial inducement of epileptiform convulsions. A clinically sound cardiovascular, pulmonary and bony system is therefore a requisite for this therapy. Speed injections are a necessity—only they will produce major convulsions. In 67 per cent of the cases positive reactions were obtained with a 10 per cent solution of metrazol, 20 per cent metrazol did not increase the incidence of convulsions. The failures in 33 per cent of the

4 von Meduna, Ladislaus. Die Konvulsionstherapie der Schizophrenie. *Carl Marhold* 1936.

duration Malzberg<sup>2</sup> of the New York civil state hospitals reported 129 per cent recovery and much improvement (271 per cent) among 1,039 patients treated with insulin

I consider sixty days the minimum for insulin treatment, with almost ninety days for older disease. Patients with early paranoid and agitated catatonic disease offer a more favorable prognosis with insulin,

TABLE 1—Comparison of Results of Insulin and Metrazol

Number of cases	Insulin		Metrazol		Insulin		Metrazol		Insulin		Metrazol	
	16	10	7	10	24	17	Illness Less Than 1 Year	Illness Less Than 2 Years	Illness More Than 2 Years	17	16	16

No improvement	5	4	3	7	14	14						
Hospitalization	6	8	3	9	20	16						

For forty seven insulin patients there were 332 treatment days with an average of 44.8 days of deep wet shock per person. The average duration of insulin therapy was 10.9 weeks.

For thirty seven metrazol patients there were 263 treatment days with an average of 17.6 convulsions per person. The average duration of metrazol therapy was 13.4 weeks.

Summary	Insulin	Metrazol
Full remission	13 (27.7%)	3 (8.1%)
Social remission	5 (10.6%)	1 (2.7%)
Improvement	7 (14.9%)	8 (21.6%)
No improvement	22 (46.8%)	20 (67.6%)

\* Relapse

whereas stuporous catatonic and depressed hebephrenic subjects respond better to metrazol. Advanced paranoid and delusional hebephrenic patients must be treated according to their response.

Since my associates and I have had no fatalities with either treatment in 173 cases in Wisconsin, I shall not enter into a discussion as to which factors may be responsible for the reported neuropathologic alterations. The cumulative effect of unnecessary continuous large doses of insulin or the severity and frequency of metrazol seizures may account for such histopathologic changes.

Clinical experience with insulin and metrazol therapy is far in advance of theory. The similarities between the two types are loss of consciousness, definite vegetative, circulatory and biochemical alterations, tonic-clonic signs with abnormal reflex actions, and recovery from induced drastic autonomic disintegration. Insulin or metrazol as an agent alone certainly does not condition the changes in the mental syndromes. The clinical manifestations caused by the two substances offer important factors in the explanation of the therapeutic mechanism. At present investigation in reference to carbohydrate metabolism and oxidation of the central nervous system are in the foreground.

Intermediary carbohydrate metabolism is still in the midst of elucidation. Any scheme offered at the moment is tentative, not final. The process function is probably similar in many essentials in both muscle and brain, there are also differences, yet the mechanisms are not certain. In cerebral glycolysis the principal substrate is dextrose, in muscle it is glycogen.

Anaerobic and aerobic phases are distinguished. The following sequence is given for muscle (Embsen): In the anaerobic phase, glycogen to hexosephosphate to triosephosphate to phosphoglyceric acid to phosphopyruvic acid to pyruvic acid to lactic acid.

In the aerobic phase, lactic acid forms pyruvic acid, which may be decarboxylated or condensed with oxaloacetic acid to initiate a circular chain of reactions in which oxidative breakdowns occur. Vitamin B<sub>1</sub> is concerned in the disposal of pyruvic acid. Whether methylglyoxal plays a part in normal glycolysis is debated, it is believed to be formed in the retardation of glycolysis by addition of bromacetic acid (Barrenscheen and Beneschorsky).

It is said that insulin blocks glycogen mobilization in the brain, liver and muscles and that toxic hypoglycemia would ensue if the body could not form sugar from fats, lipids and proteins. By medical termination of hypoglycemia at the proper time, toxic reactions can be avoided. This has not been done in most shock experiments, therefore one should not form absolute conclusions from the picture of insulin hypoglycemia in animals and assume similar organic abnormality in human beings.

A split product of sugar metabolism, the triose methylglyoxal,<sup>9</sup> deserves special attention as a possible causative factor in the production of neural and psychic symptoms during hypoglycemic insulin shock therapy. Almost immediately after intravenous injections of

small amounts of methylglyoxal the animals present severe and bizarre psychomotor excitability, with tonic distortions, grimacing, noisy respiratory and masticatory phenomena, salivation and incontinence. If the blood sugar content of animals had been depleted, this symptom complex would progress to a convulsive status with

9 Fischler F and Hirsch O. Wirkung einiger Abbauprodukte des Traubenzuckers bei Störungen des Kohlenhydratstoffwechsels. Ztschr f physiol Chem 165: 287-307 1927. Fischler F and Lindner A. Weiteres über Zuckersplattung unter der Wirkung stark verdünnten Alkali. ibid 175: 237-247 1928.

death It is possible that in insulin therapy at the low point of hypoglycemia and the high peak of alkalosis, methylglyoxal exerts a toxic effect on the autoregulation of metabolic centers For a certain time, at least these dysfunctions can be tolerated or become adjusted by a compensatory endocrine sequence mechanism

The function of insulin is only beginning to be clarified Its action in decreasing the blood sugar content has been explained by an increase in the rate of tissue oxidation and inhibition of glycogenolysis (or increase in glycogenesis), a decrease in liver glycogen being considered secondary to the hypoglycemia Vendeg asserted that the factors mentioned are insufficient to account for all the sugar which disappears during insulin therapy and offered evidence that there may be a considerable transformation in the liver of glycogen to fat An *in vitro* effect of insulin has recently been demonstrated for the first time (Krebs) The preparation has been shown to have a catalytic action on the oxidative breakdown chain referred to previously (pyruvic, oxaloacetic, citric, ketoglutaric, succinic, fumaric, malic, oxaloacetic)

The amount of glycogen in the brain is small and relatively constant, decreasing only with large overdoses of insulin (Kerr<sup>10</sup>) The free sugar content of the brain is also small, but labile The brain is believed to depend for its carbohydrate on a constant supply from the blood stream Its sugar content is constantly less than that of the blood except in extreme insulin hypoglycemia, when the true blood sugar content may fall to zero Decreased oxygen uptake by the brain during insulin therapy has been reported from analyses of blood (Dameshek, Myerson, Stephenson, Himwich, Bowman, Fazekas, Wortis) and from *in vitro* studies (Holmes<sup>11</sup>) This decrease in utilization of oxygen with hyperinsulinization is probably secondary to lack of carbohydrate due to hypoglycemia

Gerard<sup>12</sup> reported from a study of brain potentials that brain cells deprived of carbohydrate are abnormal and discharge excessively Derangement of intracellular carbohydrate metabolism with accumulation of normal or formation of abnormal intermediaries (pyruvic acid, methylglyoxal<sup>7</sup>) has been suggested as a possible cause of the observed and striking cerebral disturbances of insulin shock In conjunction with this question, Demole<sup>13</sup> noted a decreased incidence of convulsive phenomena during insulin therapy in rats treated with vitamin B<sub>1</sub> and cited Freudenberg's work

Available laboratory tests which objectively support the degree or profundity of the insulin and metrazol remissions are (1) comparative studies of wave rhythms in electro-encephalic graphs<sup>14</sup> and (2) determination of the oxygen concentration ratios in arterial and venous blood

In conclusion, I wish to state that the results of the two forms of treatment of schizophrenia are encouraging and that either therapy should be started early and be extended over a sufficiently long period A definite opinion as to duration of the remissions cannot be given

at present The two methods have furnished abundant clinical and laboratory research problems, they have greatly stimulated the interest in psychiatric clinics and they have altered by refreshing, stimulating activity the fatalistic attitude toward mental diseases of the medical and nursing staff in state institutions

## TREATMENT OF THE PSYCHOSES WITH INDUCED HYPOGLYCEMIA AND CONVULSIONS

RICHARD H. YOUNG, M.D.

AND

G. ALEXANDER YOUNG, M.D.

O'LAHA

In this paper we present our results with the hypoglycemic treatment of seventy patients with schizophrenic reactions We have selected this group because it constitutes our first year's experience (October 1936 to October 1937) and because it offers an opportunity for consideration of the late as well as the immediate results of treatment In addition, we report our experience with the use of metrazol for twenty-one patients with depressive psychoses We have used metrazol for schizophrenic patients in a variety of combinations with insulin which we shall describe, however, in this paper we are placing chief emphasis on the employment of metrazol as a pharmacologic adjunct in the depressions

### HYPOGLYCEMIC METHOD

During the first year in which we utilized the hypoglycemic method seventy patients satisfactorily completed an adequate period of treatment As we reported last year,<sup>1</sup> there were two deaths in the course of treatment, but there have been none since in a larger series, 135 cases We have classified the immediate results in four groups (1) remission, (2) incomplete remission, (3) improvement, and (4) no improvement Under remission we classified those cases in which schizophrenic symptoms disappeared and adequate emotional response insight and capacity to return to former work were recovered We classed the remission as incomplete when one of these requirements was missing

We present the results in table 1 In over half the cases (forty-three) the psychotic symptoms were of less than one year's duration, and in this group results of treatment were significant The lack of remission of disease of over a year's duration was striking There was only one remission in such a case, while the remission rate when the disease had lasted under one year was 56 per cent Although the total number of cases was not large, it is of interest that our immediate results compared closely with those in the larger series, 495 cases, reported by Muller<sup>2</sup> at the Swiss Psychiatric Congress in May 1937

While there is time for no more than a superficial accounting of our work, a review of the cases in which remission was attained suggests that the best responses were in those of short duration and sudden onset, with a history of remission from a prior psychotic episode in those of vivid delusional content, with features of

excitement, and in those of disorganization of personality, which might be in part attributed to a strong affective force other than depression. It is our impression, however, that the hypoglycemic method does not affect any specific type of psychobiologic functioning.

One of the important questions that remains to be answered concerning the hypoglycemic treatment relates to the permanence of the remission. An inquiry into our group reveals that of the thirty-two patients who achieved either complete or incomplete remission eleven have shown some transient or more permanent return of psychotic symptoms. At the present time but three of the eleven patients are in psychiatric hospitals, and one committed suicide by drowning a year after discharge from the hospital.

A review of these cases fails to bring out any common factors that predispose the patient to relapse. Our statistics would indicate that the less complete the remission, the greater the tendency toward reappearance of psychotic features. This tendency toward relapse would seem to indicate that the change in personality functioning produced by the hypoglycemic method fails to offer any special outlook for the future. It is impossible to disregard the psychopathologic basis of schizophrenia and the important facts of the patient's life, the past and present situations.

USE OF METRAZOL IN SCHIZOPHRENIA

The literature that has reviewed the use of the hypoglycemic and the convulsive therapy has dealt largely with one method to the exclusion of the other. The statistical results of the two methods compare closely. Little literature has dealt with the use of insulin and metrazol in combination. It has been our belief that both drugs are efficacious, and our more recent interest has been directed toward developing plans of treatment that would utilize a combination of the two.

We have used metrazol in eighty cases to produce convulsions, with no serious complications. In the schizophrenic group we have used insulin in conjunction with the metrazol, and we have combined the two drugs in different ways to develop five different plans for treatment. We feel that the different groups of cases are too small to invite statistical comparison, so we shall merely describe our plans of treatment.

In the first group were patients who, after approximately three weeks on insulin, failed to show progress and were then given a series of metrazol convulsions. We make this change when a long period of private psychiatric care is impossible for financial reasons, because it has been our experience that the majority of patients who do well with the hypoglycemic method show some improvement in the first three weeks of treatment. It is also our belief that in some cases such a period of treatment with the hypoglycemic method is of particular benefit. This may be illustrated by the case of a 19 year old girl in whom a schizophrenic reaction with both hebephrenic and stuporous features developed. During phase 1 of the insulin treatment mild coryza developed, and we produced two convulsions with metrazol as a substitute for the hypoglycemic method. Neither at this time nor subsequently with the insulin-produced coma did she show any change in behavior. However, after a series of fourteen comas in which she showed increasing insulin sensitivity we gave metrazol again. She demonstrated a profound change in behavior after the

first convulsion, and a remission promptly occurred. To patients who fail to respond after the change to metrazol we give alternate weekly courses of insulin and metrazol, as in the "block" method described by von Braunmuhl.<sup>3</sup>

We gave a second group of schizophrenic patients metrazol after their failure to attain coma on a dose of 200 units of insulin or over. We used metrazol in such cases as a less dangerous medicament.

To a third group of patients we have given small doses of insulin in addition to the metrazol. We have added insulin to the treatment of these patients because in our early experience of giving metrazol alone we found that some who showed no progress made prompt improvement when we added the insulin.

In the fourth group are included patients to whom, during the usual course of insulin therapy, we gave metrazol twice a week, approximately one and a half hours after a shock dose of insulin. By this method we largely alleviated the fear of the metrazol treatment, a comparison of these patients at a later date with those who have shown fear will allow some evaluation of the role that is played by this affective force.

TABLE 1—Results in Seventy Cases of Schizophrenia Treated with Insulin Between Oct 1 1936 and Oct 1, 1937

Duration of Symptoms	Number of Cases	Remission		Incomplete Remission		Improvement		No Improvement

Total								25	7
Symptoms of relapse								8	3
Hospitalized at present								2	1
Suicide								1	

In the last group are patients to whom we gave metrazol after they failed to improve on a full course of insulin. This additional attempt with the pharmacologic method has seemed justified by the results obtained. Of a group of eight such patients one obtained remission, a second incomplete remission, four had some improvement, three of them only temporarily, and two showed no response.

USE OF METRAZOL IN DEPRESSIVE PSYCHOSES

While the therapeutic use of convulsions induced by metrazol has been to date largely confined to the schizophrenic group, there is no reason to believe that its efficacy should be restricted to any special type of personality dysfunction. We have observed a patient, cachectic because of hypernephroma with metastasis to the brain, who after a week of delirium had a series of convulsions. On recovering from the post-convulsive stupor he was for several days oriented, no longer fearful and, strangely enough, partially relieved of pain temporarily.

Last summer, after using metrazol in cases of schizophrenic reactions, we tried the convulsive therapy for affective psychoses. The first patient with depression for whom we used this type of therapy was a 44 year old woman who had an agitated depression of two years' standing. This patient had been hospital-

3 von Braunmuhl A. Die Insulinschockbehandlung der Schizophrenie. Berlin: Julius Springer, 1938.

ized after a suicidal attempt and, in spite of eight weeks' treatment with usual methods, was well ruttid in her depressive reaction, with harping hypochondriacal beliefs and fixed ideas of the hopelessness of her situation. We gave her metrazol, she had six convulsions and left the hospital well, after a period of treatment of eighteen days. Because of this fortunate result and subsequent favorable responses, we gave metrazol in selected cases of depression, twenty-one in all. In this series we noted an improvement in all but one case, that of a man of 54, in a second depression of two years' duration, who showed marked psychomotor retardation and loss of interest but relatively little display of depressive affect. However, a patient with a somewhat similar depressive reaction (case 11, table 2) showed a good result from metrazol after a five week period of hospitalization with no improvement resulting from the usual methods of treatment.

described by Muncie,<sup>4</sup> seemed to improve rapidly. The presence of schizophrenic features or catathymic material also seemed to affect the response unfavorably. This method will not merit a universal application and will be open to criticism as too aggressive and dangerous for the treatment of conditions that are for the most part benign and offer a favorable prognosis with more orthodox plans of therapy. In spite of our favorable results, we feel that metrazol should be used in the depressions as an adjunct, and that the necessary psychotherapeutic attention should be given the personal-emotional and situational factors after the pharmacologic phase has been terminated. However, one of our difficulties has been to interest the patient after recovery (due to metrazol treatment) in psychodynamic features to be considered if recurrence is to be avoided. As with schizophrenic patients who show remission with metrazol, patients with depression who recover have mostly a rather superficial, objective type

Average number of convulsions				7	Recovery	12	Improvement	9	
Average days of treatment				21.6	Marked improvement	6	No improvement	1	

The results, as shown in table 2, were complete restoration of a normal feeling of well being, a disappearance of all psychotic symptoms and recovery of ability to reassume past activities in twelve cases. Six patients were markedly improved by the treatment. Two were improved and gradually recovered subsequently. To date only one patient has relapsed. The duration of the psychosis affects the prognosis, but not as markedly as in the schizophrenic group.

Perusal of table 2 reveals that the number of convulsions given was less than usually given in cases of schizophrenia, and it has been our experience that improvement is usually noted after the first or second convulsion. The average number of convulsions produced was seven. The economic aspect of this method of treatment should be stressed. The period of hospitalization has been greatly reduced, the average period of treatment in the twenty-one cases was 21.6 days.

The cases of depression in which metrazol was given were not particularly selected and represent a variety of reactions. The age range was from 21 to 60, with about equal distribution between the third, fourth and fifth decade of life. Our experience suggests that the more marked the affective features, the better the response to treatment. The presence of anxiety in the depressive setting seemed to affect the response to metrazol adversely, although tension depressions, as

of insight. With a return of well being they focus their attention on reconstructive plans which will allow the best possible adjustment in future life situations.

COMMENT

In commenting on this report of clinical results, we feel that a statistical evaluation of the pharmacologic methods is difficult. Problems arise because of the

TABLE 3—Results in Twenty-One Cases of Depressive Psychoses Treated with Metrazol

variety of case material, the judgment of the examiner, the possibility of dissimulation on the part of the patient, the variance in the degree of insight and the task

4 Muncie, Wendell. Depressions with Tension. Their Relation to General Problem of Tension. Arch Neurol & Psychiat 32: 328 (Aug) 1934.

involved in a quantitative consideration of the amount of return of emotional response

The use of these methods carries the danger of arousing special interests along associated biochemical, physiologic, psychologic and neuro-anatomic lines. While such studies are necessary and informative, one should attempt to understand the changes of functioning of a part in terms of the integrative relationship of all the parts. There is also the danger of disregarding former disciplines and replacing them with a set of facts based on new methods of treatment. We feel that, no matter how striking the results of any special method, treatment of psychiatric disorders must continue along broad lines which focus the interest of the physician on the patient as a psychobiologic unit with complex sets of integration, functioning in a variety of life situations, past, present and future.

### ABSTRACT OF DISCUSSION

ON PAPERS OF DR REESE AND DRS RICHARD H AND  
G ALEXANDER YOUNG

DR A A LOW, Chicago. It is gratifying to witness the sound conservatism of the authors, especially in view of the exaggerated claims still made by some European workers with regard to rate of remission. The experiences of the Youngs with the metrazol treatment of depressive psychoses coincide fairly well with the results obtained at the Psychiatric Institute of the University of Illinois. Aside from persons with depression we have treated a number of manic patients and six patients suffering from psychoneuroses sufficiently severe to warrant commitment. The results were generally satisfactory. Our report was given in the April 1938 issue of the *Archives of Neurology and Psychiatry*. Dr Reese emphasized the lack of theoretical knowledge concerning the newer treatments. However that our practical knowledge is also insufficient is evidenced by the general lack of agreement on such important issues as the number of times hypoglycemia should be induced, the optimal length of coma, the advisability of combining metrazol with insulin and, last but not least, the method of estimating the rate of remission. At the Psychiatric Institute we had an interesting experience with regard to spontaneous remissions. To avoid selection we gave treatment to every admitted patient who did not suffer from an organic syndrome. In addition, to weed out candidates for speedy, spontaneous remission we insisted on a four week waiting period prior to treatment. Of 108 patients scheduled for treatment twelve experienced remission during this waiting period. Had they been treated our rate of recovery would have been padded by more than 10 per cent. To obtain reliable information on the effectiveness and durability of post-therapeutic remissions we induced our patients to form an organization with an abominably long name, Association of Former Patients of the Psychiatric Institute of the University of Illinois. The association, founded in 1937 is growing and has for its main purpose the elimination of the stigma attached to mental disease. The members plan an employment agency and have already secured the support of local business leaders. The first issue of a bimonthly bulletin is ready for print. Its name 'Lost and Found' was suggested by a patient. Its columns will be devoted to a fight against the stigma and will contain contributions from both patients and physicians. The patients' contributions to the forthcoming first issue are conspicuous for moderation in tone and significance of statement. The association meets twice a month at the hospital in the presence of the staff and owing to these biweekly conferences, we claim to have as reliable information as possible concerning the quality of the remissions.

DR TITUS H HARRIS, Galveston, Texas. Insulin therapy has been in use at the Galveston State Psychopathic Hospital since March 1 1936 and metrazol therapy since July 15 1937. The results in 106 cases of schizophrenia treated with insulin compare favorably with those reported elsewhere. Among thirty one cases of illness lasting six months or less there

were seventeen, or 54.83 per cent, good remissions—remissions and incomplete remissions combined—and, during a follow-up period of from three to eighteen months, thirteen, or 44.83 per cent, were still good. In only two cases of remission classified as complete did relapse occur. Follow-up studies also showed that relapses were more frequent among patients showing less complete remissions. My associates and I have used the various combinations of insulin and metrazol described here, with the exception of the combination-summation method, and have obtained beneficial results in many instances. We have also given metrazol during the course of insulin treatment, giving the shock dose of insulin immediately after the seizure in cases in which a good coma was not produced with a high dose or in which no further improvement was shown with insulin alone. I wish to emphasize the statement of the Youngs that patients who fail to have comas on doses of 200 units or over of insulin should be given metrazol instead, because it is less dangerous. Our studies of metrazol show that six patients were improved who had not been benefited previously with insulin. Of thirty-eight schizophrenic patients treated with metrazol, sixteen were benefited and twenty-two not benefited. The results show that of seven cases of recent disease treated with metrazol good remissions occurred in three and improvement in two. In one case the improvement continued and is now classified as a social remission. This gives a good remission in four, or 57 per cent (cases of recent involvement), which compares favorably with the results with insulin. It shows further that chances for a favorable outcome decrease markedly after eighteen months. Our experience with other reaction types has been limited, but thus far work along these lines has proved encouraging. I agree with the Youngs that while metrazol may bring about recovery in these cases it should be used only as an adjunct and that psychotherapy is still necessary.

DR A C BENNETT, Omaha. I wish to report my experience with metrazol, similar to that of the Youngs, in twenty-one cases of pure affective disorders of the depressive type. My patients were somewhat older. There were twenty-one with depressive psychosis whose ages ranged from 29 to 68. The majority of them were in midlife or the presenile period—eight were past 55. The psychoses were classified as of manic-depressive, reactive and involutional type. The duration averaged eight months for the manic-depressive, six months for the reactive and twelve and one-half months for the involutional type. The average doses of metrazol were 6 or 7 cc and the average number of convulsions produced was five. The days under shock treatment were fifteen, twenty and nineteen. All twenty-one patients showed improvement within two weeks after convulsive shock treatment began. One relapsed to a manic state. Dr W D Wright of Omaha made electrocardiograms for eighteen of these patients. Seventeen showed no clinical evidence of heart disease. One had rheumatic heart disease with mitral stenosis but no history of congestive failure. Five had suggestive but not conclusive evidence of disease of the coronary artery. In none of these cases was the original pattern changed by shock therapy, and the ages varied from 29 to 68, seven being past 55. Repeated electrocardiograms following treatment demonstrated abnormality in only one case. This study suggests that in this older age group the treatment may be given with safety.

DR EMERICK GRIFFIN, Greenwich, Conn. The basis of application of the metrazol convulsive procedure with the manic-depressive psychoses after its use in schizophrenia may not be construed as wholly empirical. Workers have recorded a statistical antagonism between the affective groups and the convulsive state similar to the theory propounded by von Meduna for schizophrenic illnesses. Many schizophrenic patients during these chemotherapeutic routines undergo definite affective reaction patterns in the form of agitation, hypomania, anxiety and the like before ultimate remission of the original schizophrenia. Finally, in many instances schizophrenia starts with a clearcut affective picture or is made up of many manic-depressive components throughout its course. The foregoing would tend to imply vaguely that there might be a common psychopathologic basis for these disorders, with

the affective reaction standing out as the more benign stage and the entire disease picture dependent on the psychologic and physiologic constitution of the individual patient. Even though these statements might impress one as syllogistic, there are no other definitely known facts on which to base the successes with the metrazol convulsive therapy other than a statistically prominent antagonism between certain functional psychoses and the convulsive state. Whereas the actions of metrazol and of insulin are known, it is not known why they produce ameliorative phenomena in the psychoses, chiefly because the actual psychosomatic interrelated factors of these psychoses are relatively little known. Concurrent with this last thought, it is advisable to note that the various so called combinations of metrazol and insulin are as yet unjustified statistically or theoretically. Scientifically, this combining of the use of two drugs whose individual pharmacology when applied to the psychoses is still nebulous provides a definite hindrance to the ultimate objectives which these drugs do to the psychoses and what is the cause of the psychoses in psychosomatic terms is derived from the use of these drugs. In broader terms, the goal should be to determine what component of these chemotherapeutic maneuvers is responsible for the amelioration of what phase of the psychosis. This cannot be achieved with agglomerated pharmaceutical shock procedures. It is believed more scientific and somewhat less hazardous to consider that these are two separate procedures: if one fails after suitable trial, the other may be employed. Logically, however, it is assumed that the metrazol procedure would be employed first, because of its simplicity and for general economic reasons.

DR G. W. HALL, Chicago. I think the possibility of mistaken diagnosis must be considered in some cases of schizophrenia. The word 'recovery' is used too freely at present because this method of treatment has not been used long enough to justify it. I am in favor of this treatment when no outlook remains except the possibility of the patient's going into a hospital permanently. Another point to be considered is the treatment after the patient has left the hospital and has had the final treatment, as far as the injections are concerned. A great deal of attention should be paid to the environment the patient is put in after treatment has been given rather than sending him back to his environment before the treatment was begun.

DR EUGENE ZISKIND, Los Angeles. Insulin therapy is bound up with the effects of hypoglycemia. On the other hand one of the primary functions of insulin is its effect in increasing the oxidation of carbohydrates in the tissues. I saw a patient last December whom I had first seen in 1930 when she had early manifestations of organic deterioration. She was then 53. During the past seven years she had undergone profound deterioration. It was impossible to keep clothing on her. She paced back and forth in her room, she soiled herself. Her conversation was limited to 'Where is pr?' and 'Where is Joe?' and she made these statements when she held these particular members of her family by the hand. She had a bedsores and a pellagrous lesion on her extremities and was profoundly emaciated. I thought her span of life under these conditions would be about two weeks. I suggested, since the outlook was so hopeless, that the patient receive insulin in large doses according to the technique of Sakel though with frequent feedings. To my surprise she gained in the first twenty-one days a pound a day, and she lost her restlessness. It was then possible to clothe her. She regained her previous habits as to toilet and she has got to the point at which she goes to the table and eats, although at times she has to be fed. About a fourth of her statements at this time are coherent and relevant, although she is still far from being well. This experience struck me as evidence that in a condition of cerebral malnutrition, insulin buffered and aided in the restoration of some of the lost function. It may have some bearing on the mechanism with which insulin acts exclusive of the 'shock'.

DR H. F. HINWICH, Albany, N. Y. Three points may be made concerning the mechanisms of insulin and metrazol treatment. A similarity of the two forms of treatment lies

in the fact that both depress the metabolism of the brain. The brain is different from other organs, using only carbohydrates to furnish the energy required. When hypoglycemia supervenes the brain is therefore deprived of its only source of energy. Cerebral metabolism is therefore depressed, and under these conditions first excitement and then coma supervene. Metrazol convulsions are also characterized by depression of the metabolism of the brain. This is not caused by a diminished dextrose uptake but by decrease in the oxygen supply. During the convulsion there is a cessation of respiratory movements, so that the arterial blood becomes venous and the brain is deprived of oxygen. Thus, the two treatments have in common a depression of cerebral metabolism. The second point concerns quantitative differences between the two mechanisms. Hypoglycemia produces a slow, gradual and prolonged depression. Metrazol convulsions on the other hand, cause a severe deprivation of oxygen and therefore necessarily must be briefer. Today we have heard that the treatments may be combined. Then the actions are synergistic. To the slow gradual hypoglycemic effect is added the brief acute deprivation of oxygen. Finally the intermediate links in the chain of events which starts with the original deprivation of cerebral energy and leads to the final amelioration in a certain number of cases are not known. However, it may be concluded that the deprivation of cerebral energy is associated with the initiation of the changes which cause the amelioration.

DR HANS H. F. REESF, Madison, Wis. Dr. Low is correct in stating that the after-care of the discharged patient is of the utmost importance and necessitates the physician's cooperation. I do not use the term 'recovery' but call restoration to mental health 'clinical remission'. Full clinical remission or social remission is preferable and the word 'recovery' should be avoided. I do not believe that the dangers of insulin are greater than those of metrazol therapy. There are better weapons for combating reactions to insulin than to metrazol, which once shot into the vein, is beyond control. I am often disturbed by the severity of metrazol convulsions. Prolonged and severe cerebral vascular constrictions may produce ischemic necrosis. It is not known as yet whether such possible necrotic infarctions are altering the metabolic anatomic schizophrenic syndrome in the brain. Petit mal reactions after injections of metrazol are said to be better than true convulsions in certain instances, especially of the incipient stages of the illness. I wonder whether the unpleasant sensations from metrazol therapy are not creating, after a certain readjustment at least, falsifications and unreliable statements as to the patient's mental health because of his aversion, apprehension and fear of the effect of metrazol. With regard to Dr. Friedman's remarks, the question of expense is no argument in any scientific evaluation of new therapeutic procedures. I am treating disorders as a physician, and the question before me is which therapy brings the best results. Therefore, metrazol should not be favored because it is less expensive. I agree that it is easier and simpler to give an injection. It requires much less clinical judgment and alertness to supervise metrazol treatment. Dr. Hinwisch remarked about the changes in the metabolism and chemistry of the brain. I am well acquainted with his excellent investigations. The deficiency and recovery phases of the chemistry of the brain are not known as yet for schizophrenia. It is not known even whether the disease is one of oxygen hunger or of overstimulation by carbon dioxide or whether the cerebral carbohydrate metabolism is affected. The question of cerebral metabolism is still in a state of flux, and it cannot be stated accurately today whether the needs for minerals, oxygen, pigments, enzymes, coenzymes and vitamins are adequate in the presence of schizophrenia. It is necessary more or less to speculate as to what may be and what may not be the factors of the energy restoring mechanism in the remittent schizophrenic psychoses. Neurologists and psychiatrists have opened with insulin and metrazol therapy a field of research which has brought the specialties into the closest cooperation with those of the biochemist, the physiologist and the internist. Only group investigations will benefit humanity in the future.

# THE CONVULSIVE-IRRITATIVE THERAPY OF THE PSYCHOSES

A SURVEY OF MORE THAN THREE THOUSAND CASES

LASZLO VON MEDUNA, M D

BUDAPEST, HUNGARY  
AND

EMERICK FRIEDMAN, M D

WALTHAM, MASS

Our purpose in this paper is primarily to present in tabular form statistics on the metrazol and camphor-metrazol irritative therapies obtained through the cooperation of seventy-five clinics. It is our further purpose to bring to the attention of the various workers in the more or less recently developed chemotherapeutic procedures certain important points regarding indications, contraindications, complications and technique and finally, certain theoretical considerations of the *modus operandi* of convulsive-irritative therapy.

## STATISTICAL SECTION

The case material shown in the tables was derived from direct correspondence with the hospitals and workers respectively listed.

For the most part these tables are self explanatory. Because of the great variability in the statistical classification of the duration of illness by the various European workers, this feature was given in terms of less or more than one and one-half years. It was rather unfortunate in a sense that a more detailed analysis of the types of illness was not available, because in view of the well known heterogeneity of schizophrenic disorders such data would have been valuable in estimating the type of disorder that seemed to respond best to convulsive therapy. On the other hand diversity of diagnostic classification in different countries and the absence of international criteria for purposes of standardization made the listing of schizophrenic subtypes difficult. For the present we must content ourselves with a study of therapeutic efficacy of the convulsive-irritative therapy in this heterogeneous schizophrenic group and the energetic proposal of international diagnostic standards. This topic will be taken up in the section on indications.

From these totals we may tersely set forth the results. Practically every existent anthropologic group with the exception of the oriental is represented in these cases. From the criteria proposed in most of the European centers at the present time the schizophrenic disorders are divided into "acute" (duration less than one-half year), "subacute" (duration from one-half to one or one and one-half years) and "chronic" (duration longer than one or one and one-half years) types. With the terms "remission" and "improvement" we refer to complete remission and great or much improvement commonly employed in most mental hospitals. Under the latter term are included the so-called partial and social remissions (table 4).

The universally better results in cases of earlier involvement are at once evident. However there are significant results in cases of chronic illness even if in these not such a bright therapeutic outlook can be

demonstrated. Persons who have undergone remissions have remained well for a period ranging from several weeks to almost four years.

On closer analysis of the fatalities, which were of minor significance, the following necropsy reports were noted:

One case of aortic insufficiency with chronic myocardial changes.

One case of bilateral hypernephroma and a compressing thyroid adenoma.

One case of pulmonary embolism from clinically unrecognized pelvic thrombosis.

One case of unknown causes.

One case of cerebral thrombosis.

One case of acute pulmonary tuberculosis (after latency).

One case of suicide.

Two cases of acute camphor poisoning.

It is to be concluded from these figures that in at least three cases the therapy could not be held directly accountable. Yet inclusive of these three the mortality stands at 0.29 per cent.

The incidence of complications was 2.2 per cent. The most frequent complication, but one which could not be numerically estimated or included, was that of temporomandibular subluxation. This occurred "very frequently" with some workers, with others very infrequently. The most important numerically designated complications were of the "mechanical" type—dislocations and fractures with or without dislocations of the extremities. The upper and lower extremities were alike involved. Next in order were the so-called inflammatory complications—the "production of, or exacerbation of, an inflammatory process." In this category were included local abscesses due to injections of camphor, "lighting up" of latent tuberculosis, pulmonary abscesses and acute (myocardial?) collapses. All of these complications will be discussed in a later section.

Concerning convulsive therapy of persons with affective psychotic reaction types, including involuntional melancholia, brief attention may be given to preliminary theoretical considerations. In a study dealing with the concurrence of epileptic convulsions in certain psychoses, Notkin<sup>1</sup> commented on the relative absence of convulsive episodes in manic-depressive psychosis, as well as in schizophrenia. The same thesis was pointed out editorially by Paskind<sup>2</sup>. Obviously, it was not unexpected that a therapy that seemed likely in one psychosis would also be employed probationally in other psychoses, e. g., fever therapy in other mental conditions besides dementia paralytica. But the aforementioned authors tend to make one consider convulsive therapy in the affective psychoses in a manner similar to that followed by von Meduna in schizophrenia viz., on the basis of the theoretical antagonism between the disease and epilepsy.

In table 3 are given the results of convulsive therapy in affective psychoses, including involuntional melancholia. The features given are self explanatory. The amount of therapy ranged between four and fifteen reactions of grand mal in all the cases.

Besides the figures in table 3 more informal reports communicated to us indicated that the results of the convulsive therapy in the affective psychoses were

decidedly positive. Some workers went so far as to state that in the depressed types the therapy acted in "almost a specific manner." It was found that 77.6 per cent of persons with affective reaction types underwent

As we consider these statistical results, the lack of concurrent control data forms the greatest objection—that these patients might spontaneously have displayed similar improvement or remission in time. This ques-

remissions (or "near" remissions) after a relatively brief course of therapy. Neither of us has had any real personal experience with convulsive-irritative therapy in the affective psychoses; what is offered here is purely caution from the experience of other workers.

tion may be given a general and a specific answer. In an entirely general manner the statistics, particularly of larger mental hospitals, before the advent of the chemotherapeutic approaches implied or stated that schizophrenia (dementia praecox) was of relatively poor

prognosis Deterioration would occur with but few exceptions. The literature was replete with statements deploring the sad outcome, the burdening of mental hospitals and the enormous cost entailed in the proportionately large intake of schizophrenic patients. Generally there was a dismal note struck in psychiatrists' minds when the diagnosis of schizophrenia was established.

Since the development of the recent chemotherapeutic procedures there have appeared with more and more frequency in the literature various workers' views that schizophrenia has not been hopeless and that perhaps there have occurred many more spontaneous remissions than has been previously believed—that these present day results are not to be attributed to the procedures—seemingly a strangely paradoxical point of view. Specifically, certain statistical evaluations of the schizophrenic disorders may be quoted, there are many other equivalent references. According to a number of statistical workers<sup>3</sup> it has been found that the rate of spontaneous remission of schizophrenic patients varies between 4 and 12.5 per cent. Schizophrenic patients are usually hospitalized for a number of years, so that as a rule more than 50 per cent of the populations of mental hospitals is made up of schizophrenic patients. One other important point. These patients who after so-called spontaneous remissions emerge from mental hospitals are not usually able to pursue their former occupations, even though they may be taken care of in their homes. It is to be noted then, that the quantity and quality of remission attained by the convulsive-irritative procedure are superior to those of spontaneous remission, and, finally, the length of hospitalization is markedly abbreviated.

If, now, we consider the affective psychoses, it is to be noted that, as they are regarded generally as having a great tendency toward spontaneous remission, the therapeutic factor then resides mainly in the shortening of the period of confinement. Unfortunately there are no definite criteria whereby one might predict the possible duration of a given affective psychosis. However some figures are available regarding the duration of psychotic "episodes" of the affective reaction type.<sup>4</sup> In a survey of some 8,000 manic-depressive patients it was found that the average duration of attacks or episodes was a little over one year, in repeated attacks the duration tended to be longer. It was difficult in that survey to estimate the duration, in certain cases in which great improvement occurred. There is known the axiomatic statement that the affective psychosis "lasts from six months to six years," but for statistical comparisons the figure in the aforementioned survey is more accurate.

If then, as noted in table 4 between five and fifteen treatments were necessary to produce a remission or "parole condition" in the affective psychoses treated a maximum period of seven and one-half weeks was necessary which should rather definitely indicate positive results.

## INDICATIONS

In the various publications relating to convulsive therapy, and likewise from the papers on the insulin hypoglycemic therapy, almost all the workers have demonstrated a tendency to depose certain criteria of specified treatment for specified types of disease. Many confusing and contradictory reports are noted, for the reason that individual clinics have not yet accumulated enough cases. Perhaps the most constant issue, if this term is permitted, arises in the treatment of stuporous disease of the catatonic type. The workers whose experience is chiefly with insulin therapy are protagonists of the opinion that this type responds best to convulsive therapy, as it appears relatively refractile in the insulin procedure. Some workers go so far as

§ No enumeration of duration 60 per cent of patients with acute disease had remissions.

to state or imply that convulsive therapy should be restricted only to this type. In fact most of the "combinations" of insulin and metrazol have been primarily directed to its treatment. In broader terms, the opinion is frequently expressed that the psychosis with a predominant picture of motor phenomena is to be handled with convulsive therapy, while the psychosis demonstrating mainly psychic phenomena (hallucinations, delusions) is to be treated with insulin. This concept is held to be basically erroneous primarily because the schizophrenic disturbance is in itself made up of both psychic and motor components in each instance, and secondarily because this schematization is unsubstantiated by experience. In the experience of some workers we note that their paranoid patients responded best to convulsive therapy and patients with hypokinetic or hyperkinetic psychosis not at all. On the other hand other workers have demonstrated exactly oppo-

site results. These two types of data are valueless for grouping statistically in order to point out indications.

Many of the workers with whom we corresponded stated that a certain number of their patients recovered under convulsive therapy after an unsuccessful insulin regimen. We ourselves have observed a number of

us in previous papers.<sup>5</sup> In table 1 an apparent remission rate of 66 per cent in twenty-seven cases of chronic disease was obtained. These results merit at least further consideration, as they indicate a further sphere of usefulness of the camphor-metrazol irritative procedure in the treatment of the chronic schizophrenic disorders.

The results of the convulsive procedure in the affective psychotic illnesses as seen in table 3, indicate a definite sphere of usefulness of this therapy—on the basis of 77 per cent rate of relatively rapid remission in 109 cases. The great majority of workers stated or implied that a rather definite ("almost specific") indication was noted in the various depressed or agitated subtypes of this group of psychoses.

#### CONTRAINDICATIONS, COMPLICATIONS, MORTALITY

The contraindications although mentioned in previous papers, are again listed and divided into absolute and relative types.

1 *Absolute Contraindications*—(a) Organic cardiovascular disease, whether arteriosclerotic, hypertensive or inflammatory, (b) acute febrile illness, (c) pregnancy, (d) active tuberculosis and (e) abnormality of the blood or urinary constituents determined by complete laboratory examinations.

TABLE 4—Results of Convulsive Irritative Therapy of Schizophrenic Psychoses

	Cases
Total number of cases	794
Total number of full remissions	737 (92.8%)
Summary of American Statistics	
Total number of cases from 57 hospital and clinic	1,462
Total number of full remissions	290 (19.8%)
Total number improved	714 (48.8%)
Acute type (under 6 months)	210
Number of remissions	125 (59.5%)
Number improved	47 (22.4%)
Subacute type (between 6 months and 1 year)	901
Number of remissions	14 (1.6%)
Number improved	47 (5.2%)
Chronic type (over 1 year)	85
Number of remissions	38 (44.7%)
Number improved	38 (44.7%)
Summary of European Statistics	
Total number of cases from 35 hospital and clinic	1,417
Total number of full remissions	441 (31.2%)
Acute and subacute type (under 1½ years)	864
Number of remissions	290 (33.6%)
Chronic type (over 1½ years)	761
Number of remissions	101 (13.3%)
(The apparent discrepancy in the total of the European figures is due to the fact that some hospitals did not give full details as to duration of illness.)	
Mortality (calculated from total number of cases tables 1, 2 and 3)	9 (0.6%)
Complications (calculated from total number of cases tables 1, 2 and 3)	6 (0.4%)

2 *Relative Contraindications*—(a) Exophthalmic goiter, (b) history of severe intracranial injury, (c) seropositive syphilis, (d) latent tuberculosis, (e) confinement to bed for one year before treatment is undertaken.

The last named condition deserves special mention. It is believed, according to the experiences of one of us, that if a patient has been bedridden for a number

\* Results not fully complete.

such cases. Whereas the aggregate of these cases displays a fair-sized sum, it is pointless to argue that, therefore, convulsive therapy is superior to insulin therapy, because a similar number of cases showing the reverse to be true could be demonstrated. What is important is that in spite of the large number of cases collected by us and the large number of cases collected by the insulin therapists, it is impossible to set forth relatively inflexible rules for specified (metrazol or insulin or both) treatment in specified cases. It is possible to state that to modern psychiatrists there are two chemotherapeutic methods, if one fails after a fair trial, the other may be employed.

What is known from the given statistics in schizophrenic disorders and what can be utilized for "indications" may be given in three statements.

1 In the acute and subacute schizophrenic disorders (lasting less than one and one-half years) remissions were obtained in nearly 52 per cent of cases. According to the workers who further subdivided their cases into acute or early types (under six months' duration) the incidence in that group amounts to nearly 60 per cent. Further, great improvement, as defined previously, was noted in an additional 20 per cent of each group.

2 The aforementioned cases included all the well known types of schizophrenic disorders, in the majority of reports no specific division was given but in occasional instances the workers stated or implied that one or another type seemed to do better with metrazol than with insulin. Conflicting reports in this respect exclude the possibility of "type-specified" therapy.

3 In chronic schizophrenia (lasting longer than from one to one and one-half years) there was a rate of remission of 10 per cent. This would have been markedly increased if the selection of cases had excluded very chronic disease, namely of more than five years' duration, which made up much of this group. Much improvement was obtained in an additional 37 per cent. Attention might be called to the apparently high rate of remission noted in the chronic group treated by the camphor-metrazol irritative routine outlined by one of

5 Friedman Emerick. Irritative Therapy of Schizophrenia. Practical Application and Theoretical Considerations. New York State J. Med 37: 1813-1821 (Nov. 1) 1937. Friedman Emerick and Ackerman A. W. The Problem of Schizophrenia. Recent Therapeutic Considerations. Clin. Med. to be published (citations from von Meduna).

of months and a considerable degree of emaciation has developed, there occurs perhaps a relative avitaminosis, reflected in osseous changes. The latter condition, and not so much the muscular pull (by emaciated muscles?) during the metrazol convulsion, is thought to be the basis for fractures of the extremities during treatment an important complication. This will be taken up in the following paragraphs.

The complications noted in the tables were conveniently divided into two groups, the "mechanical" and the "inflammatory." The first group was made up of dislocations and fractures with or without dislocations. This does not include the numerous temporomandibular dislocations which were replaceable without difficulty or sequelae. The second group consisted of pulmonary abscesses, activations of latent pulmonary tuberculosis, acute (myocardial) reactions, local (camphor in oil) abscesses and severe camphor intoxications. Numerically stated, the complication rate was

Total "mechanical" complications, thirty-five (11 per cent)

Total "inflammatory" complications, thirty-three (11 per cent)

Total complications, sixty-eight (22 per cent)

There are several known means whereby these "mechanical" complications may be overcome. In the first place, as noted previously, the emaciated bedridden patients who are to receive treatment ought to be regarded as suffering from possible avitaminosis—a possible disturbance in calcium metabolism. Before active convulsive therapy is begun, it is recommended that the patient receive several months' standard intensive vitamin and calcium treatment. Second, certain technical details are suggested. In larger hospitals where many patients are treated at a time the patients are brought to a treatment room, given their convulsion and then wheeled out either on the same bed or on a stretcher cart and thus transferred to an adjoining "recovery" ward. In either event it must be remembered that the patient is not fully conscious and must be handled as though he were emerging from anesthesia. Care must be taken lest one or another limb dangle over the side of the bed and be dislocated by its own weight. Likewise, care must be taken during the postconvulsive period of excitement or restlessness that in thrashing about the patient does not get his limbs caught in the various parts of the headboard and footboard of the bed or get them entangled in the bedclothes or even underneath his trunk. At times during this postconvulsive state the patient may dislocate his shoulder by attempting to lift his body off the bed by rising up on his arms. In a similar manner the hip may be dislocated in this period by attempts to raise up the body on the legs or by gross kicking movements. Subluxations may occur also during the tonic-clonic phases of the convulsion, and these are not easily guarded against. However, it is possible to study the particular motor pattern of each patient during his first reaction. This motor pattern is usually repeated at each successive treatment. With adequate knowledge of the underlying mechanisms of various dislocations and fracture dislocations, an attempt may be made to prevent their occurrence by supporting the joints that appear vulnerable in the particular motor pattern that the patient displays. One single important direction is to prevent abduction of the limbs.<sup>6</sup> As an added

precaution it is well to examine the patient immediately after the clonic phase of the convulsion and apply the various tests for dislocation of the limbs. If this has occurred, it is possible usually to relocate these joints while the patient is still partially unconscious and thus avoid undue stretching of the ligaments as well as operative procedures after the patient is awake.

In order to lessen the frequency of dislocations of the jaw, several suggestions are offered. If the patient has been known to dislocate his jaw easily before the treatment is started, or if the patient is very prognathous, it is well to place the gag in his mouth before the injection and employ a Barton bandage or similar appliance to prevent the mouth from opening too wide during the convulsion. This may also be done manually by one of the nurses or attendants. In the event of dislocation, the jaw may be replaced before the patient regains consciousness. A simple presumptive test of dislocated jaw after a therapeutic convulsion is to observe whether the mouth is still open or whether the gag can be easily removed after the clonic phase. In the latter case it is to be strongly suspected that the jaw is dislocated, and attempts at relocation should be started immediately.

To point out briefly the possible preventive measures against so-called inflammatory complications, we must consider first that the absolute and relative contraindications are important to exclude before treatment is undertaken. The patient must be carefully examined for any evidence of illness, laboratory examinations must be complete, and thoracic roentgenograms, as well as electrocardiograms, made if at all indicated.

The occurrence of pulmonary abscesses (in 0.1 per cent) are thought to be due to aspiration, infarction and transitory pulmonary edema during the convulsions. If the treatments are administered to a healthy person (free from cardiac and respiratory disease of any type) and if an absorbent gag, made of cellulocotton or a similar substance to absorb orotracheal secretions, is employed, this complication ought to be minimized. In several hospitals either a hard rubber gag is used or one made of several wooden tongue depressors wrapped in gauze; both of these are believed inadequate. Another precaution is to give the treatments only if the stomach is empty, preferably before breakfast, to avoid the aspiration of regurgitated material. Some workers placed the blame for the pulmonary complications (and possibly the cerebral in one case) on the loosening of a thrombus from the antecubital veins, which became inflamed as a result of the treatment or possibly of local mechanical irritation because of the struggles of the patient against injections. This factor cannot be overlooked.

The occurrence of gluteal abscesses in the course of camphor therapy is understandable because of the large amounts of camphor in oil solution necessary to produce the camphor effect. However, their occurrence is greatly reduced if the area of skin is prepared as though for a surgical procedure and thorough deep massage administered locally for at least fifteen to thirty minutes. Hot sitz baths several times daily during the treatment are also helpful.

There were noted one case of nonfatal and two of fatal acute camphor intoxication (0.1 per cent). From the experience of one of us a suggestion is offered to avoid a fatal outcome. The patient will display extreme lassitude, the pulse and the respiratory rate

<sup>6</sup> This suggestion was offered on consultation with Dr. S. A. Thompson of Greenwich, Conn.

will become markedly increased, persistent leaden cyanosis will be noted and physical examination usually will reveal evidence of bronchiolar or pulmonary inflammation (The chief route of excretion of camphor is believed to be the respiratory tract.) All these symptoms come on gradually over a period of several days. Relatively rapid antidotal action was noted to follow utilization of oxygen (tent) and intravenous administrations of hypertonic dextrose solution.

The cause of the acute (myocardial) collapses, non-fatal, is at present unknown to us. Numerically they play a rather insignificant role (0.06 per cent).

The mortality rate of 0.29 per cent and the causes of death have been mentioned. The possibility of reducing mortality to a minimum by following the listed and implied contraindications is self evident. Even as it stands, however, the mortality rate is entirely negligible.

#### TECHNIC

It is assumed that the reader is already familiar with the technical details of the metrazol therapy and the camphor-metrazol irritative modification which have appeared in previous papers.<sup>6</sup> However, certain recent developments have been noted especially in the field of concurrent psychiatric management, which in turn revolves about the associated anxiety on the part of the patient against the treatment and the personal contacts that the patient has with the treating physician. Before taking up these questions, we will outline some recent administrative features of the treatment.

From the experiences of a number of workers with the metrazol convulsive therapy it was felt that once the convulsive responses were established they should be kept up throughout the course of the treatment. In other words, it is believed harmful if the patient does not experience a grand mal type of reaction at each period of treatment. This conclusion was arrived at after a number of patients who were progressing nicely suddenly had relapses after subconvulsive or "petit mal" doses. For this reason the present technic was outlined as follows:

The initial dose of the 10 per cent aqueous solution of metrazol is from 3 to 5 cc intravenously. If a convulsion does not take place within a minute, another injection of 1 cc more than the original amount is given. If again a seizure does not result, the treatment is taken up the following morning, beginning with 1 cc more than the last dose. This procedure is repeated until a convulsion results. Third injections are usually not given unless there is a great degree of psychic upheaval or considerable "death anxiety." Even in cases of the most resistive type a convulsive reaction will occur on the third or fourth day of treatment at the most. As high as 46 cc has been given in a single period in increments of 16 + 16 + 14 cc without deleterious effects on the cardiovascular system, but the case was one of extreme resistance. To the physician already well acquainted with the various phases of the convulsive therapy more latitude is offered. In the latter instance larger increments are injected if no signs of a forthcoming seizure are noted. For example, if after a 5 cc injection no pupillary dilatation or tremors of the orbicular, oral or facial muscles are noted, and if there is no alteration in the consciousness of the patient, another injection of 6.5, 7 or even 8 cc may be given within the next minute. However, the latter more flexible procedure of judging the increments by the signs displayed by the patient should be

employed by physicians who have already had considerable experience with the convulsive therapy. It is urged that physicians who are just beginning to employ this treatment should follow a rather rigid rule of increasing doses, as mentioned in previous papers.

The procedure employed by some workers in allowing the needle to stay in the vein and raising the dose by increments of from 2 to 3 cc until a seizure results is regarded as somewhat hazardous from the standpoint of producing mechanical inflammatory changes, leading to thrombosis.

The use of an absorbent cylindric mouth gag about 15 cm long and the thickness of the finger is advocated. The protection of the patient's limbs has already been mentioned. It is further to be noted that the patient's head is not resting on the hard bed supports before the injection is given.

The use of sedatives during the treatment should be restricted only to cases of repeated convulsions either with metrazol or with camphor. If the general condition of the patient appears satisfactory, three or four individual convulsions are not regarded by us as harmful. If the convulsions tend to continue beyond this number or if they tend to merge, intervention is necessary. This may be controlled by the intravenous use of standard barbituric derivatives, hypodermic administration of morphine and atropine, rectal administration of ether or avertin with amylene hydrate or inhalations of ether, chloroform or ethyl chloride.

The anxiety of the patient against the treatment is frequently mentioned by various workers, the reasons are numerous. As inner causes there are the feelings of impending death and sudden annihilation during the phase of the aura. It is found that most patients will have rather complete amnesia for all this anxiety after a grand mal reaction but that the anxiety will often persist if the patient does not undergo a convulsion. Preliminary work of a varied nature is being carried on in a number of centers with the goal of eliminating this aura phase. Some workers combine insulin with the metrazol for this purpose, others administer nitrous oxide, analgesia and still others give scopolamine. Withal there is this point to recall. It is not known what particular phase of this therapeutic convulsive syndrome plays the important role in producing remissive changes in the psychotic organism. It is not altogether excluded that this very anxiety and fear might possibly be just as important as the other phases of the convulsion. In line with this are the experiences of one of us with the camphor routine. Beneficial effects with this drug have been noted without actual motor phenomena and with the predominant features of anxiety mounting to panic. Another interesting point we offer is that ambulant patients have been treated, some even coming distances of 30 to 125 miles to the hospital willing to receive the treatments. Home treatment has also been administered but is not recommended for general application because of the existing hazards already mentioned and the relative impossibility of managing postconvulsive excitement.

It is considered rather unwise from the standpoint of the anxiety of the patients to treat them singly in separate treatment rooms. It is felt that under such conditions the patients fear the going or being forced to go into this room. The various fears and forebodings inherent in the psychosis become prominent when the patient is led or dragged into a room where several

persons await him, he is put into a bed, and a table with various instruments is prepared. He undergoes a terrifying experience during the treatment and finally awakes in another room.

A suggested procedure used in the Angyalfold Institute, Budapest, may be described. The patients are led in a group of about twenty into a large ward. They all lie down in beds and wait for a little while. The physicians and necessary attendants come into the room and in an entirely matter of fact almost banal manner treat the patients in turn. The whole procedure should be calm and commonplace. No remarks with regard to the condition of the patient should be made by either the physician or attendants within the hearing of the patient. Naturally, it is unwise for one patient to see another during the convulsion, and for this purpose a simple portable screening arrangement is used. To the sides of the bed posts are attached tin sockets so constructed that a supporting rod may be inserted at the foot and head posts, between which a canvas curtain may be stretched. This appliance is attached to the beds on each side of the one in which the patient is being treated. A removable foot board partition is put in and there is completed the so-called metrazol room, which is movable from patient to patient and gives sufficient room to work around each. Without any haste, even taking into consideration the factor of repeated injections in some cases, twenty patients may be treated in an hour.

The frequency of the injections, as gleaned from the different workers, varies from daily to weekly. From our experiences and those of others, it is recommended that at least two convulsive reactions a week be induced. In many instances remissive changes do not become manifest until the second day after the convulsion—after the immediate effects of the convulsion have worn off. This event ought to be awaited in the proper management of the frequency of injections. If the patient does not respond or if he responds only for a brief interval after the injections (less than twenty-four hours) the injections may be given every other day. If a response indicative of remissive changes in the motor or psychic manifestations endures for a longer period than mentioned, convulsive reactions ought to be induced less frequently, but responses ought to be obtained at least twice weekly.

The question arises as to the number of seizures necessary before treatment is terminated. For this no definite answer is available. It is naturally not advisable for a fixed number of convulsions to be predetermined for a given patient. Yet, in spite of the fact that there is no analogy for this in the field of medicine, some workers have actually stated that a given patient will get only a certain number of seizures (five or ten) and no more. If the patient relapses in these instances the treatment (again predetermined) will be resumed. As a general rule it has been found helpful to induce a minimum of about twenty-five reactions of grand mal type before abandoning treatment in cases of failure to respond. Patients who respond should be treated until the maximum improvement or remission can be noted. Then, it is believed, three or four additional seizures should be induced to prevent the possibility of a relapse.

A few technical remarks of general and practical nature in the management of camphor therapy may be given at this point. Whereas the routine dosage has been previously mentioned, the general condition of the

patient with special reference to the cardiovascular and the respiratory system should be observed—undue fatigue, prolonged cyanosis and associated signs—before the dose is increased as rapidly as previously designated (1 to 2 Gm of amorphous camphor daily in two doses). Furthermore the occurrence of gluteal abscesses must be suspected if rise in temperature occurs during the treatment, temperature should therefore be taken at least three times a day. Other recommendations are deep muscular injections after careful preparation of the skin and deep kneading massage after the area has been covered with an alcohol-soaked cloth. After the massage the patient must be protected against assaultive or suicidal attempts due to the camphor effects. This is accomplished usually by moderate restraint (shoulder and foot type), somewhat loose so that the limbs will have enough play during the convulsive reactions and yet tight enough to prevent a sudden lurch or leap from the bed. This restraint is necessary for at least three hours after each injection. Meals should consist of liquids in the morning and evening, the "heavy" meal should be at noon. Additional nourishment (if the patient is underweight) may be given late in the evening.

In the face of the foregoing data and statements, we do not purport to state or imply that the convulsive irritative procedure is *the* method of treatment of the psychoses. It is not forgotten for an instant that the schizophrenic (and the affective) psychosis has psychopathologic and pathophysiologic components. It is taken for granted that the psychiatrist will enroll the patient in the various occupational, recreational, reeducational routines as soon as it is deemed advisable. The factor of psychotherapy likewise is not discarded and the patient left to work out his difficulties by himself, even though many will say that this will cloud the real therapeutic factor. A full or complete remission cannot be said to have occurred unless there is complete insight and until the patient has satisfactorily worked out and assumed a critical attitude toward his pathologic experiences. This working out of the pathologic experiences is the main purpose of the psychotherapeutic procedures, about which in turn, revolves the great difference in rates of remission reported by different workers. It was noted that many patients, particularly with the acute type, appear to be able to and actually do, work out their psychologic difficulties to a satisfactory and socially acceptable conclusion. However, this chance should not be taken, because too many known psychologic factors are interwoven with the psychotic disease process. Much informative data which may later be employed in the after-care of the patient can be obtained in the concurrent psychotherapeutic interviews. The character of these interviews is bound to differ in the hands of different workers so that specific formulations cannot be given and only some workable suggestions are offered. Psychotherapeutic advances should not be forced on the patient, rather these advances should lag behind the progress of the patient. The phenomenon of temporary amnesia for recent psychopathologic manifestations on the part of the metrazol-treated patient should be taken into consideration and on the basis of previous experiences should not be forcibly penetrated nor should the patient be subjected to rigid cross examination as to his past behavior. Even the most delicate resistance by the patient should not be overcome by direct means, he should be approached

with caution until ready and awaiting explanations and even then should not be shocked or startled by the physician's answers or explanations. As already reported by one of us,<sup>7</sup> the patient comes to the office for psychotherapy at every four to five seizures. The first period is usually given over to orienting the physician by superficial, general questions as to whether any alteration has occurred in the psychic status of the patient. If no change can be detected the interview is terminated in a few minutes. If the patient brings up any information relative to any alterations, the discussion proceeds according to the nature and intensity of these changes. For example, if the patient comments or shows that he no longer has auditory hallucinations, he is asked how this happened. For this there is usually no answer and it is then explained that if he actually "heard sounds," one could not have caused their disappearance with injections. In this way a causal association between any improvement and the injections is fostered. In subsequent interviews the character and makeup of hallucinatory and delusional data are brought up and thoroughly discussed, with such technique as the physician has generally used in individual cases. Pathologic experiences are explained gradually to the patient instead of his being allowed to explain them to the physician. It is usually noted that the hallucinations and then the delusions of reference disappear first. If the predominant picture was one of autism or rigid catatonia, these features usually become replaced at first with flightiness or anxiety. Some of the explanations offered by patients during these interviews are to the effect that they "feel as though awakened from a dream." They compare the illness with a "visit to the theater," recognizing some of the unrealities at times by "feeling as though every one were playing a part, acting, and so on." In many other ways it is evident that they try to avoid or ease themselves out of an apparently disgraceful state of mind. The physician, then, has to strive until the goal of "mental illness" is established in the patient's mind. Much reassurance, symptomatic explanations on the basis of "functional disturbances" and, above all, a strongly hopeful attitude are all in order.

#### THEORETICAL CONSIDERATIONS

It is useful in this section to differentiate between established facts and theoretical conjectures. Both are necessary in the development of a therapeutic procedure, but it is somewhat difficult to delineate between the two. Almost since the beginning of the application of the convulsive therapy to the psychoses, it has come frequently to our attention that this therapy ought to be widely applied in the field of psychopathology as an agent to "frighten a patient to his senses" or to "scare the devil out of him." To the scientific minded this expression harks back to medieval times and ought not to be employed in scientific discussions.

The fundamental basis of the convulsive-irritative therapy is the statistically significant biologic antagonism between the epileptic state and schizophrenia previously reported.<sup>8</sup> The basis of this therapy has become much contested of late, many physicians recalling from their experience many cases and instances that would tend to disprove the theory. However, at the present time no definite factual evidence has been offered that

would displace this concept. Whatever might be the biochemical significance of this apparently reversible antagonism is as yet unknown. The actual underlying biochemical processes responsible for the epileptic state and the pathobiology of the schizophrenic state are alike enigmatic.

Whereas it has not yet been proved or disproved how the psychobiologic factors of shock to the organism act, these factors are of themselves somewhat abstract and equivocal. Various types of shock procedure have been used in the past to alleviate the psychotic illness, with indeterminate and nonprecise effects. Some patients have improved after undergoing various physical illnesses, the great majority of psychotic patients who undergo the same illnesses do not appear to be helped. Just what are the healing factors in these illnesses and the shock procedures used in the past is difficult to ascertain. Psychiatrists have repeatedly stated that if a patient is threatened with death and annihilation all the "imaginary" symptoms will disappear and efforts will be made on the part of the organism to protect itself—this feature is the most fundamental law of life and forms the basis of efforts at reconstruction. Others have struck at the problem analytically and brought up theories of satisfaction of sadistic-masochistic tendencies and parent transferences in seeking the aid of the physician to help the patient maintain his existence. Other theories parallel those aforementioned and describe the psychobiologic reaction of the seizure as carrying the partially fulfilled death wish of the patient to a satisfactory symbolic conclusion, whereat reconstruction begins. It is, however, impossible in the scope of this paper to discuss all these and we must therefore restrict ourselves to more of a physiologic explanation of what happens to the central nervous system during metrazol (and camphor) therapy and then draw theoretical deductions therefrom.

Instead of the attempts to localize the action of metrazol as selective of the frontal pole (von Angyal<sup>9</sup>) or by vasospastic-anoxic cortical changes noted in insulimized animals (Stief<sup>10</sup>), it is correct to note that the pharmacologic action of metrazol is that of medullary stimulation and irritation, autonomic response and dilatation of the blood vessels of the brain (Fischer and Lowenbach, Hildebrandt<sup>11</sup>). Also, according to the works of Hildebrandt, metrazol produces an increase of discharges from the cerebrum and improved circulation in the brain independent of changes in blood pressure. Metrazol is believed also to have as its action the release of certain elements of the reflex arc, which action is believed to occur in the arc element preceding the

pyramidal tract In patients in whose blood the venous oxygen content is reduced metrazol has been found to increase this by improving the circulation and respiration by stimulation of the vasomotor and respiratory centers in the medulla<sup>11</sup> Pathologic examinations of animals deliberately poisoned with metrazol (von Meduna<sup>12</sup>) showed diffuse cellular changes, most prominent in the medulla and then in order of severity in the cells of the spinal cord, midbrain and cortex The vascular system was intact It was concluded that metrazol acts primarily as an ectodermotropic drug by direct cellular action Recent work on the respiratory metabolism of brain tissue showed that metrazol produced a temporary oxygen deficiency of the brain cells and that its convulsive action is dependent on this feature<sup>13</sup>

From these data, together with the observation of certain workers that schizophrenia is associated with a low rate of oxygen consumption<sup>14</sup> and relatively sluggish autonomic activity, it is possible to theorize that the medullary irritation with resultant respiratory, vasomotor and autonomic responses is the basis of the metrazol convulsive therapy The vasomotor response in particular seems to be the subject of relatively insufficient attention In line with this thought it is to be recalled that recent studies on the action of carbon dioxide on the central nervous system showed it to be primarily a vasodilator and circulatory stimulant (to provide more oxygen to more brain tissue by enlarging the vascular bed and volume of blood in the brain<sup>15</sup>) This in itself may possibly be the basis of the transitory improvement noted in schizophrenia after inhalations of carbon dioxide If now we consider that the underlying action of metrazol is in part that of dilatation of the blood vessels of the brain, the mechanism of influence would be similar to that of carbon dioxide but more profound In addition there is also a direct stimulating action on the cellular elements of the central nervous system, so much so that the patient cannot of his own volition control his thoughts and actions under the influence of high doses

The action of camphor is less clearly defined In the aforementioned studies of cellular metabolism and pathology this action was observed to be entirely similar to that of metrazol When given intravenously, camphor also produces epileptiform convulsive reactions<sup>16</sup> Yet clinically by intramuscular injections camphor has a decidedly different action Anxiety mounts to panic and is associated with assaultive or suicidal behavior a rather typical deliriform confused state in which reactivity to vivid motile hallucinations may occur Patients who are undergoing camphor therapy often lose all semblance of a fixed schizophrenic state and display a picture more closely resembling the acute psychotic

pattern All of this may possibly be a drawn-out convulsive effect resulting from slower absorption of the camphor It is believed that the "slow motion" picture of the convulsion appearing with camphor will prove valuable in studying the phases of the seizure that may be the basis of the healing factor in the convulsive-irritative therapy

How these data may be applied to the use of convulsive therapy in the affective psychoses is problematic It is known that persons with some affective reaction types become afflicted with schizophrenia—or, in the minds of some workers, the disorder was basically schizophrenic It is also known that many schizophrenic features are shown by many affective psychotic patients indicating vaguely a common psychopathologic basis in these instances An interesting recent chemotherapeutic development was the finding that many schizophrenic patients displayed typical affective reactions in the form of hypomania, agitation, depression and the like as early transitional phenomena before remission How much these pertain to the treatment of affective disorders is at present not known

## VESICAL DIVERTICULUM

### A FEATURE STUDY

ROBERT V. DAY, M.D.

AND

HARRY W. MARTIN, M.D.

LOS ANGELES

The importance of vesical diverticulum is emphasized by the fact that badly infected, poorly draining diverticula, with the resulting stagnation and eventual ammoniacal urine, give rise to subjective symptoms not exceeded in severity by those of advanced vesical tuberculosis, carcinoma or calculus

Vesical diverticulum is a form of herniation through points of weakness between muscular fibers interlacing at approximately a right angle These so-called weakened spots may be due to embryologic defects or, presumably, may result from pathologic changes in the bladder wall produced by infection, inflammatory changes and back pressure In practically every case there is evidence of increased intravesical pressure over a long period, almost always caused by obstruction at the bladder outlet With few exceptions prostatic in one form or another, is present and accounts for the back pressure, without which there would be no diverticulum The dictum that two factors, weak spots and obstruction, are necessary for the production of diverticula is well borne out In the rare cases in which an obstruction cannot be diagnosed there is a probability that abnormal intravesical pressure on voiding is nevertheless present

Of our sixty-nine patients forty-two had contracture of the bladder neck, twenty-five benign hypertrophy, one congenital valves in the posterior portion of the urethra and one (a syphilitic female) a filiform stricture in the urethra The slow long-continued and milder obstruction due to contracture of the bladder neck or median bar is much more apt to result in

diverticulosis than is the large adenomatous prostate. Although statistics differ somewhat it may be stated that approximately 95 per cent of all vesical diverticula are complications of prostatism while the remaining 5 per cent occur in women and boys. Urethral stricture in women and congenital valves and other obstruc-

Fig. 1 (case 1)—Two large diverticula; the upper is intraperitoneal and the lower overlaps the bladder.

tions of the posterior part of the urethra or bladder neck in boys are the determining factors.

Diverticula differ widely in many of their anatomic characteristics. They may be single or multiple. Sixty-eight per cent of Judd and Scholl's 133 patients had only one diverticulum; 12 per cent had two and 7 per cent had three. This is important because the results of excision are not good if more than two sacs are resected.

In approximately 75 per cent of cases the orifice is situated from 1 to 3 cm above the interureteral ridge, either mesal or lateral to the ureteral meatus. In other cases it may be high up laterally or in the dome.

The sacs vary from hazel-nut size to giant diverticula with a capacity of 2 liters or more. Small diverticula are of little importance if the obstructing lesion is overcome, otherwise they grow though slowly. The most important factor is drainage, that is to say how well the sac empties during the act of voiding. There is some stasis in all diverticula which have attained considerable size. Large sacs with relatively small orifices however empty so poorly that they are termed retention diverticula; the stasis predisposes to infection, especially when one of the urea-splitting organisms is involved.

In contradistinction to the site of the orifice, the direction of the protrusion varies. The sacs may extend between the rectum and bladder nearly as far as the subpubic ligament and in addition well up on the superior surface of the bladder. In one patient with two large sacs one rose vertically upward in the peritoneal cavity like an inverted pear and was completely and intimately covered by a peritoneal coat

(fig. 1). Another unusual type is a small shallow diverticulum (presumably arising from an accessory ureteral bud), situated just a few millimeters lateral to one ureteral meatus. In one case what appeared to be a sclerotic process in a small, wide open depression of this kind was believed to be the obstructing factor producing a large hydronephrosis on that side.

Diverticula with openings high up sometimes suggest the hourglass type (figs. 2 and 3). Usually the walls are composed of all the coats of the bladder, whereas sacs arising near the ureteral meatuses tend to have fibrous walls lined with epithelium.

In one typical hourglass bladder (fig. 2) a carcinoma developed in the upper segment. In one patient with a very small shallow diverticulum, one could visualize through the cystoscope a papilloma a little larger than a pea. Radon seeds were implanted in the papilloma. This patient was apparently cured, having been lost sight of after one year. All told, we encountered intradiverticular neoplasms in four cases.

In three cases one or more intradiverticular calculi occurred, and in two others calculi were found in both bladder and diverticula.

The symptoms of diverticulosis are varied and are not pathognomonic. Ordinarily pronounced prostatism with infection stands out. When a patient voids and in a short time is again able to void a considerable amount of diverticulosis is suggested. If there is little or no residual urine, there is no diverticulum of consequence. If every patient with a urologic complaint is accorded a urologic examination which is adequate, comprehensive, methodical and in keeping with the complaint, there will be few mistakes as to either the underlying or the associated lesions. With diverticulosis one is almost certain to encounter considerable residual urine. In men this usually spells prostatism, and every patient with prostatism should at some suitable time have a cystogram.

In order to obtain optimum visualization a series of cystograms are helpful, viz. (1) a plain anteroposterior exposure of the bladder distended with radiopaque solution, (2) a contrast cystogram and (3) an oblique view. Sometimes an air cystogram is revealing and has the advantage of outlining the prostate. Simple cystoscopic examination, a routine procedure for almost all urologic

ills, completes the diagnosis and also reveals the nature, size and location of the obstruction. The clinical signs of prostatism are usually present—nocturia, hesitancy and small stream. Infection is often superimposed, resulting in various degrees of pyuria, frequency and dysuria. Sometimes a cystic tumor can be felt in the abdomen. Once infection occurs, especially with a urea-splitting organism, the

Fig. 2 (case 2)—Hourglass bladder with carcinoma in the upper segment.

disuria may become as severe as that associated with advanced tuberculosis, carcinoma or large calculus of the bladder

#### TREATMENT

The first and fundamental consideration is the surgical relief of the obstruction. After this has been accomplished, the diverticulum will seldom increase in size whereas there is a progressive enlargement of the sac if this is neglected. If the sac is not large, empties fairly well and is not badly infected, diverticulectomy is unnecessary in many instances. On the other hand, if the diverticulum is of the retention type or is large, excision is indicated provided the patient is a fair surgical risk. Advanced myocardial or cardiovascular disease, extensive kidney damage with markedly lowered function, asthma and bronchiectasis are contraindications to diverticulectomy.

Almost every author cites a patient or two with a giant diverticulum who suffered little and went along for years with little or no therapy. One must bear in mind, however, that in such cases (with the diverticulum usually associated with contracture of the bladder neck rather than with benign hypertrophy) there has been no infection. Giant diverticula like giant hydronephrosis, attain such great dimensions because they have escaped infection for a long period. If infection occurs, subjective symptoms begin, peridiverticulitis ensues and the patient promptly seeks relief. All diverticula become infected sooner or later, and the optimum time to excise large sacs is before they become badly infected. Our experience has been that the very large diverticula are easily removed because of absence of peridiverticulitis and firm adhesions. In excising a diverticulum the sac is freed by blunt gauze dissection just as is the sac of an inguinal hernia. We have discovered no easier method. This operation is often most difficult because of dense adhesions. When the sac is freed all around down to the neck or diverticular orifice, it may be inverted into the bladder and excised and the rent sutured with chromic gut. If inversion should prove difficult, it may be excised extravasically. An abundance of rubber drains (rubber tissue or Penrose) should be inserted between the bladder and the peritoneum and laterally. Gauze packs will often be necessary to control the oozing. The cystostomy opening in the bladder should be partially closed by suture.

In many cases a three stage operation is advisable, that is to say, a preliminary cystostomy drainage is performed with or without drainage of the diverticulum itself by means of an accessory Pezzer catheter introduced through the diverticular wall. In due course this is followed by diverticulectomy and finally by the surgical attack on the obstruction. The order of the last two procedures may be reversed. In most instances we feel that it is unwise and an unnecessary surgical risk to excise the sac and attack the obstructing lesion at the same sitting, so to speak. When both diverticulectomy and a prostatic operation are done it is often a problem to decide on which to do first. From a purely technical consideration primary excision of the sac is the logical procedure, but in many cases preliminary cystostomy drainage spells a lowered mortality rate. When cystostomy has been done on a previous occasion, it may prove troublesome because of the inability to find and enter the plane of cleavage between the sac and the surrounding structures. Again, with a cystostomy and a collapsed bladder the diverticular orifice is practically closed (partly by contrac-

tion and partly by collapse and distortion), and as a result the diverticular contents in the retention type become truly putrid in a few days. Hence, especially when dealing with huge sacs, we have introduced an additional drainage tube into the sac itself at the most easily accessible site. One way to avoid the necessity of direct tube drainage of the sac itself is to adopt the trocar method of preliminary cystostomy. With the Day trocar, a 22 Pezzer catheter is easily introduced into the bladder with the aid of local anesthesia. With this technic there will be absolutely no leakage around the catheter even when the bladder and diverticulum are filled to capacity. This having been done, the bladder and diverticulum are distended with a dilute solution of one of the organic silver compounds and the fluid is allowed to drain, this procedure is repeated at least three times. It is advantageous to have the nurse perform such irrigations twice a day.

Fig. 6—Giant diverticulum

Squire's operation is a relic of pioneer days and is no longer employed by its originator. It has given poor results at our hands.

Divulsion of the orifice and its resection with a McCarthy loop, cautery or scissors are mentioned only to be condemned. Such procedures invite urinary extravasation and panpelvic sepsis. Moreover, if the patient escapes these complications little benefit can be expected and this only temporarily.

We have studied sixty-nine cases of vesical diverticulosis in twenty-five years. In fifty-one operation was performed for relief of obstruction at the bladder neck and in thirty-two diverticulectomy was performed. Of the latter prostatectomy was done in seventeen, resection of the bladder neck in fourteen and electrodestruction of congenital valves in one. The resections of the bladder neck included both open operations with Young's punch and transurethral resection with a McCarthy loop. It is amazing to observe the degree of sclerosis at the vesical outlet in patients with giant

**diverticula** The bladder neck is like cartilage, sclerotic tissue having replaced the internal sphincter and adjacent prostatic tissue to such an extent that when sufficient tissue to relieve the obstruction has been excised the patient may be left with a measure of incontinence.

There were three deaths, and in three other cases the results were poor. In one of these cases the ureter

Fig. 8 (case 6)—Stone formation in sac eight years after prostatectomy.

opened into the diverticular sac, and in another four diverticula were excised, leaving a small contracted bladder.

Diverticulectomy often proves to be a very difficult operation and to be followed by a stormy convalescence, although the mortality should be less than 10 per cent. Most deaths occur in the urologist's first half dozen cases. His mortality will drop with technical experience, especially when he has learned which patients are not suitable candidates for this operation. The good results have been permanent, some of our patients were living fifteen or more years after excision of a large diverticulum.

#### SUMMARY AND CONCLUSIONS

1 Obstructions should be looked for in every instance of vesical diverticulosis. Surgical relief of the obstruction is the prime consideration. In about 95 per cent of cases either a benign hypertrophy or contraction of the bladder neck is found and must be overcome by prostatic resection or prostatectomy. Congenital valves in boys are easily destroyed through a McCarthy miniature cystoscope. Most obstructions in the female urethra are easily dealt with.

2 If the sac is large or of the retention type, diverticulectomy should be performed in addition to surgical relief of the obstruction. Otherwise the patient is condemned to endure one of the most distressing of all urologic ills.

3 Diverticulectomy is apt to be followed by poor results when a ureter opens in the sac or when more than two sacs are excised. Small diverticula should not be resected.

4 Notwithstanding every effort in the matter of preoperative preparatory treatment, many patients continue to be such poor surgical risks that operative measures, especially diverticulectomy, must be abandoned. One must then resort to such palliative measures as fit the case.

5 Because of the technical difficulty and oftentimes stormy postoperative course, diverticulectomy is a much neglected operation. Due consideration of the patient's well being calls for a certain degree of boldness.

#### REPORT OF CASES

**CASE 1**—J. F., a mining engineer aged 62, had all the symptoms of advanced prostatism. Cystoscopic examination revealed contraction of the bladder neck and two diverticula. The orifice of one sac was situated near the left ureteric meatus, the sac itself protruding over the posterosuperior surface of the bladder. The second diverticulum opened into the dome and protruded directly upward into the peritoneal cavity and was everywhere covered by an intimately attached peritoneal layer (fig. 1). A suprapubic incision was made down to, but not into, the bladder itself. From a study of the cystogram (fig. 1) an unusual type of protrusion was suspected, which led us at the very outset to explore from within the peritoneal cavity before opening the bladder. The sac was found to be entirely intraperitoneal and surrounded everywhere by an intimately attached peritoneal coat. This coat was circumcised at the diverticular neck and the sac inverted into the bladder. The bladder and peritoneum were separated from each other for a distance of about 3 cm. from the diverticular neck. Both openings in the peritoneum were then sutured and the bladder was opened. The second diverticulum was then freed everywhere down to its neck and inverted into the bladder. Both sacs were excised from within the bladder and the openings closed with chromic gut. The sclerotic bladder neck was then attacked with a cold steel punch (Young's) until the obstruction was overcome. A small Pilcher bag was introduced to control hemorrhage and the cystotomy incision partially closed. Rubber tissue drains were introduced extravasically both laterally and on the superior surface of the bladder. The patient was completely cured and has had no urinary disturbances during the intervening four years.

**CASE 2**—G. L. T., a cinema director aged 39, first seen Sept. 7, 1920, had had frequent urination, dysuria and occasional gross hematuria with clots for several years. For the past three years he had suffered from pain on the right side low in the flank which became progressively worse. The urine contained albumin, pus and a green streptococcus. Stereocystograms (fig. 2) demonstrated an hourglass bladder, with the upper half set at approximately a right angle forward to the lower half, in just about the same space relation that a normal uterus bears to the vagina.

Study of the kidneys disclosed a pyonephrosis on the right side. Nephrectomy on the right side, to be followed in a few weeks by amputation of the upper segment of the hourglass bladder, was advised and was performed.

Five weeks later ureteral obstruction on the left side had developed, accompanied by pain, tenderness, severe constitutional symptoms and almost complete anuria. The ureter was blocked at its intramural portion owing (as was later discovered) to carcinomatous infiltration.

Feb. 4, 1921, through a perirectus incision the left ureter was transplanted into the skin of the abdomen. The ureter was distended to the size of a thumb above an area of stenosis and contained purulent urine. After the transplantation, the phenolsulfonphthalein output rose rapidly. Three weeks later a

Fig. 9 (case 7)—Diverticulum on right side due to congenital valves.

mass developed which could be easily palpated above the pubis and bimanually with a finger in the rectum. The bladder was occluded at the constricted site of the hourglass and the upper segment filled with exudate, which under pressure periodically discharged into the lower segment. March 8 the upper half of the bladder was resected and found to be grossly carcinomatous, with thick, irregular outgrowths from the mucous membrane, which infiltrated the wall of the upper half of the hourglass and histologically was medullary carcinoma. Seven months later the patient died of carcinomatosis.

CASE 3—C C W, a physician aged 66, first seen Dec 19 1921, with a temperature of 102 F, had had symptoms of prostatism for several years and difficulty in urination for the past ten days, after catheterization and prostatic massage performed elsewhere. The bladder could be felt suprapubically nearly to the umbilicus principally on the right side. The patient himself had suspected for some time that this mass was a hydronephrosis, although it was low. He was hospitalized and the bladder gradually decompressed by an indwelling catheter. December 17 a cystogram (fig 3) was made; the diverticulum apparently was situated anterolaterally. The afternoon temperature remained above 102 F for ten days notwithstanding the use of an indwelling catheter. A mass the size of a goose egg persisted on the right side, although the bladder was kept empty after the first two days. After a rigid examination it was believed that the constitutional symptoms were caused by the retained contents in the diverticulum. Accordingly on the following day suprapubic cystotomy and excision of the diverticulum was performed. The wall of the diverticulum was thick and contained all the coats of the bladder. The sac contained 70 cc of purulent urine and the opening into the bladder was so constricted that it could not drain. The fever promptly subsided and prostatectomy was done one week later. The patient was alive and well four years later.

CASE 4—F P, a man aged 44, seen in consultation with Dr Buie Garstang and Dr Eugene Hoffman had badly infected and ammoniacal urine. The nonprotein nitrogen content was persistently above 50 mg despite drainage with an indwelling catheter for six weeks. The phenolsulfonphthalein output was low and there was a marked lag. He had two large sacs (fig 4) with an estimated capacity of 350 cc each. We felt that a transurethral resection would be fatal and diverticulectomy was absolutely taboo not to mention ureteral transplantation into the sigmoid. We did feel that the patient could survive cystostomy, local infiltration anesthesia being used but this would have resulted in a collapsed bladder with consequent retention and stasis in the diverticula. We agreed that infection in the bladder and diverticula could be cleared up if we sidetracked these structures by means of bilateral extraperitoneal ureterostomy to the skin. As in this operation there is no exposure or handling of any viscus it is practically without shock and no appreciable amount of blood is lost. A small rubber catheter introduced into each ureter up to the renal pelvis draining into a thin-walled pure gum bag keeps the patient dry and is the surest way of eliminating renal infection. This operation was subsequently performed by Drs Garstang and Hoffman with complete relief of the distress.

CASE 5—W T, a man aged 54 consulted his brother who is a physician, because of a painless cystic mass in the abdomen. After palpating and percussing the abdomen the doctor introduced a catheter and withdrew 2,400 cc of clear urine. Cystoscopic and cystographic examination revealed a giant diverticulum (fig 5) and obstruction of the bladder neck.

With local anesthesia and through a suprapubic incision one Pezzer catheter was introduced into the bladder and another into the diverticulum through its wall. Eight days later the diverticulum was excised and the bladder neck resected by means of a cold steel punch. Because of the friability resulting from the preliminary drainage operation there was some difficulty in finding the plane of cleavage. Once it was found, however, there was surprisingly little difficulty in

freeing the sac. The internal sphincter was invaded and replaced by rigid scar tissue and because of its cartilaginous density was resected with difficulty. Microscopic examination of the tissue resected from the bladder neck revealed an almost complete absence of muscle fibers. The patient resumed his occupation in due course but wears a rubber urinal during the daytime because of incontinence.

CASE 6—J M, an attorney aged 64, seen Dec 8, 1919, presented on the right side of the trigon, mesially to the right ureteral meatus a small shallow diverticulum with a relatively large neck, through which the distal wall could be plainly viewed. There were several cellulæ on the left side. Cystographic examination likewise showed only a small diverticulum. The residual urine amounted to 160 cc. The prostate was much hypertrophied. The patient postponed prostatectomy for eighteen months. Cystograms made at intervals during this period showed a gradual increase in the size of the sac. March 20 1921, prostatectomy was performed. Five years later he appeared with two calculi of buckshot size which he had voided. Roentgenographic examination disclosed about twenty calculi of like size but cystoscopic examination showed only two in the bladder. Through a catheter his bladder was distended and he was caused to assume a knee elbow position for a few moments. By this means, most of the calculi escaped into the bladder and were easily removed. Repetition of the procedure enabled us to recover the remaining calculi. After a few months the same sequence occurred. He later made a trip abroad, and on his return he had approximately twenty good-sized calculi in the diverticulum, they were too large to pass through the diverticular opening into the bladder (fig 8). In November 1929 diverticulectomy was performed, after which he had no residual urine until January 1937, when he suffered mild hemiplegia. He now has 25 cc of residual urine. He is 83 years of age.

CASE 7—N W, a boy aged 5½ years who had been treated for enuresis for several weeks in the outpatient department of the Los Angeles County Hospital, gave a history of being unable to void at will, of wetting the bed and of pain in the end of the penis. This condition was sometimes worse and sometimes better but in the last few weeks the enuresis had become markedly worse. The abdomen was of the protruding type but there were no tender areas. Percussion and palpation revealed a distended bladder. A small catheter was passed with difficulty and 450 cc of residual urine was obtained. Cystourethroscopic examination revealed valves in the posterior portion of the urethra, and a cystogram demonstrated a large diverticulum on the right side (fig 9) but no ureteral reflux. The kidney function was low and the patient was suffering from what in effect was prostatism. Drainage was continued for a number of weeks by an indwelling catheter until the kidney function was normal. Feb 2 1926, the bladder was opened suprapubically, the diverticulum freed and excised and the posterior portion of the urethra dilated with a small uterine cervix dilator. Later, when the suprapubic opening became small the remnants of the valves were destroyed by means of high frequency current through a No 16 McCarthy cystourethroscope introduced through the external meatus into the posterior portion of the urethra. The boy made a good recovery, emptied his bladder, had clear urine and in 1927 had more than made up the year in school which he had lost by reason of his illness. This is the only case, so far as we know from the literature available in which diverticulum resulted from congenital valves. This patient now 18 years of age has clear sparkling urine and no residue.

---

**Relative Weights of Atoms**—By careful experiments the relative weights of the different atoms have been established, the atom of hydrogen—the lightest of all—being taken as unity. Thus the atom of nitrogen weighs 14 times that of hydrogen, the atom of oxygen 16 times, the carbon atom 12 times. Examples of heavy atoms are platinum 198, gold 199, lead 207, uranium—the heaviest of all—238—Bosanquet W Cecil Meditatio Medici Aldershot Gale & Polden, Ltd, 1937

## LARGE SOLITARY SEROUS CYSTS OF THE KIDNEY

REPORT OF THIRTY-TWO CASES INCLUDING TWO  
CASES CURED BY ASPIRATION AND INSTILLATION  
OF 50 PER CENT DEXTROSE SOLUTION

GEORGE WINTHROP FISH, M.D.

Associate Professor of Urology Columbia University College of  
Physicians and Surgeons

NEW YORK

Cysts of the kidney vary from microscopic to tumor-like proportions. The cysts with which I am here concerned are solitary cysts which vary from 6 to 28 cm in diameter, contain clear fluid and are situated in or on the parenchyma of the kidney. They have an irregular lining of low cuboidal epithelium and are in no demonstrable way connected with the pelvis, calyx or ureter of the kidney in which they are found. Hemorrhagic, multilocular, hydatid or retention cysts due to obstruction of calices or other pathologic conditions are not considered nor is cystic degeneration of the newborn or polycystic kidney disease.

The historical and literary background of such cysts is interesting. Cystic disease of the kidney was noted 300 years ago, but no clear-cut classification of the various types was made until 1876. In spite of the comparative rarity of the condition, more than 700 men have written about it. Pathologic studies, clinical observations and extensive reviews of the literature form the bulk of the material. Experimental studies

the earlier years, leads one to exclude more than half as not complying with my definition.

The cause of solitary cysts is uncertain. Three outstanding theories, supported by experimental work and embryologic investigation, are current: (1) congenital origin (Kampmeier, 1923), (2) vascular damage plus tubal blockage (Heppler, 1930) and (3) embryonal rests (Latteri, 1930).

Heppler and Latteri have experimentally produced cysts similar to those in man. None of these theories, however, seems to cover all the possibilities, and as it is not my intention to give a detailed discussion of etiology

Fig. 1 (case 11)—Bilateral pyelogram showing large cyst in the upper pole of the left kidney with compression and distortion of the calices (Aug. 27, 1934).

make up but a small part. Moreover, although 300 solitary cysts have been reported, careful examination of the reports, particularly of autopsy reports made in

From the Squier Urological Clinic, Presbyterian Hospital, Columbia University.

This series comprises private and ward cases; my colleagues of the clinic allowed me to use their cases.

Read before the Section on Urology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

Fig. 2 (case 11)—Renal cystogram and pyelogram showing cyst after withdrawal of 360 cc of fluid and injection of air (Sept. 10, 1934). Air injection was for the purpose of determining rate of refilling—not as a diagnostic or therapeutic procedure.

I shall sum up by quoting a physician who, with enlightful but questionable logic, said that "the origin was multiple."

The pathologic anatomy is of interest. The majority of the cysts are closely adherent to, and often partially surrounded by, renal tissue. They are rarely completely lined with epithelium, and when present it is usually of a low cuboidal type. The remainder of the cyst wall is composed of fibrous tissue consisting of several layers of cells, not well supplied with blood vessels, and occasionally calcified. The renal tissue in contact with the cyst wall usually shows atrophic changes or evidence of low grade chronic irritation. The cyst wall is almost without exception densely adherent to the kidney substance, a matter of some importance from the therapeutic standpoint. The content of the cyst is usually a clear amber fluid with a specific gravity of from 1.002 to 1.010. It contains chlorides, albumin, globulin, epithelial cells, a few lymphocytes, leukocytes, and occasionally a few red cells. There may be faint traces of urea. These observations have been reported, and my own corroborate them.

### GENERAL CONSIDERATIONS

**Incidence**—This is extremely variable. For years no solitary cyst may be seen in one locality or clinic, and then unexpectedly a few are encountered. None, for instance, were seen at the Brady Institute of John-

Hopkins Hospital in 12,500 urologic cases up to 1926. My associates and I, on the other hand, observed thirty-two between May 1928 and May 1938. These were encountered in a group of 11,879 urologic cases, in 4,011 of which the involvement was renal.

*Age*—The youngest patient in our series was 19 and the oldest 72. In the literature one finds cases of solitary cyst of the fetus reported, and patients have been as old as 92. The average age in our group was 53, which corresponds with that in other reported series.

*Sex*—The condition has been slightly more common in females than males in previously reported series. In our series the incidence was about equal in the two sexes.

*Site*—The predominant location is the lower pole. Our observations agree with those of other clinicians in this respect. We observed fifteen cysts in the lower

except in one case in which there was marked ptosis of the kidney, were absent.

Three patients themselves noted a mass in the abdomen. Examination revealed a mass in the kidney region or below it in eight other cases. In the remaining twenty-one cases no mass was palpable.

Fig 3 (case 11) —Lateral view of renal cystogram showing slight fluid level.

pole, eight in the upper pole and nine in the central portion of the kidney. The number for the central portion is larger than has been reported elsewhere. Fourteen cysts were found in the right kidney and eighteen in the left. In two cases the involvement was bilateral.

*Size*—The largest cyst in the series contained 10 liters and the smallest approximately 350 cc.

#### SYMPTOMATOLOGY

The duration of the symptoms varied from one day to twenty years. About one half of our thirty-two patients had symptoms referable to the cyst, which is unusual as compared with other reports. The predominant symptom was pain or discomfort on the affected side. Other symptoms were those usually associated with any large abdominal or retroperitoneal mass, i. e. gastrointestinal disturbances of varying degrees. Urinary symptoms directly referable to the cysts,

Fig 4 (case 11) —Normal outline of kidney and expansion of calices (Oct 6 1937). Exploration with an aspirating needle resulted in a dry tap.

Fig 5 —Pyelogram of right kidney showing a tremendous cyst of the lower pole of the kidney and medial displacement of the organ with compression and distortion of the calices (August 1937) the patient was a woman.

#### DIAGNOSIS

In every case in our series there was evidence of disease in the affected kidney. This evidence consisted of (1) change in the outline of the kidney, (2) a smooth,

usually globular, shadow at the top, middle or bottom of the kidney in some cases of less density than the kidney shadow itself, (3) change in shape of the calices in the form of compression or clubbing, and increase in the size of the pelvis, (4) abnormal motility of the kidney (five cases), and (5) change in position of the normal axis of the kidney, or partial rotation

## COMMENT

In view of the foregoing facts, three questions present themselves 1 Can a positive preoperative diagnosis of solitary cyst ever be made? 2 What is the best form of treatment? 3 From what types of surgical procedure may one choose?

According to my experience the answer to the first question is no

Operation is the treatment of choice except when contraindicated by associated disease which makes a

able information as to the rate of refilling of the cysts I used this treatment for the first time in 1934 and for the second time in 1936 Both patients were cured

Excision was used in seventeen of our cases, nephrectomy in ten and aspiration in two In three cases no

Fig 6 (same case as in figure 5)—Renal cystogram and pyelogram showing air filled cyst after withdrawal of 1200 cc of fluid and injection of air (August 1937) After a diagnostic renal cystogram 100 cc of 50 per cent dextrose was injected into the cyst Within a few days the cyst partially refilled in large part because of the action of the dextrose Five hundred cc of fluid was aspirated A dry tap was performed in February 1938

major operation inadvisable Surgical intervention obviates the possibility of mistaken diagnosis and eliminates any risk that an unrecognized tumor in the cyst will be overlooked

The exact procedure to be employed will of course depend on the operative appearances, but in the vast majority of cases simple excision of the free portion of the cyst wall and treatment of the adherent remainder by phenolization or the use of Zenker's solution will be sufficient

When a kidney badly damaged by infection or other pathologic change is encountered, nephrectomy is the obvious procedure

Aspiration, followed by the instillation of a sclerosing material, such as 50 per cent dextrose, gives excellent results when operation is not deemed advisable It brings about immediate relief of pain and in two of our cases resulted in cure Our cases of cyst treated by aspiration are illustrated in figures 1 to 7 and give valu-

Fig 7 (same case as in figures 5 and 6)—Pyelogram of kidney with normal outline of kidney and normal position and expansion of calices (February 1938) Exploration with an aspirating needle resulted in a dry tap

Fig 8—The patient was a woman A few red blood cells were found on routine urinalysis The history was unimportant Pyelograms made at intervals over three months showed no change in the size of the mass at the upper pole or in the outline of the calices At operation a malignant carcinoma was found and nephrectomy was performed

treatment was given, because of the presence of other more serious conditions The nephrectomies were done in the early years of the series With an increasing knowledge of the pathologic process and the clinical progress, they became less frequent

The extreme difficulty of making a preoperative diagnosis is well exemplified by the case illustrated in figure 8, in which the clinical history, roentgenograms and laboratory examination all pointed to the presence of a cyst. Operation disclosed a highly malignant carcinoma of the upper pole of the kidney.

Operation when feasible is indicated and when contraindicated, exploration of the suspected cyst with the aspirating needle through the loin should be done, aspiration offering relief of symptoms, and the possibility of cure should a solitary cyst be found. The danger of spreading a malignant process or producing infection with the aspirating needle is negligible.

### ABSTRACT OF DISCUSSION

ON PAPERS OF DRS DAY AND MARTIN AND DR FISH

DR ALFRED I FOLSOM, Dallas, Texas. A few fundamental matters in handling diverticula are their size, the size of the opening, the infection and the coexistent urethral obstruction.

is generally fibrous. Crenshaw stated the opinion that three women compared to ninety-seven men have diverticula. I have had three patients within the last few years who must have had the diverticula occur within twelve hours previous to reporting, for they gave a history of straining to void, followed by severe pain over the region of the bladder, and the passage of bloody urine. Cystoscopic examination showed blood-stained edematous mucosa surrounding a diverticular opening. A man of 22 was seized during sexual intercourse with a severe pain in the region of the bladder. Morphine gave him no relief. Cystoscopic examination at the hospital showed multiple diverticula, one in the prostatic urethra extending under a prominent median bar. Draining his bladder through the cystoscope gave no relief, and it is interesting that suprapubic cystotomy gave no relief, for he came from under the anesthetic in as much pain as before the bladder was opened. It was noted in draining the bladder suprapubically that the wall had excessive muscular development, and exploration of the different diverticular openings showed the one opening on the right wall of the bladder near the ureteral orifice to grip down like a rectal sphincter when the finger was introduced. I concluded that the diverticulum on that side could not empty

### Summary of Cases

Case	Date	Age	Sex	Site*	Symptoms and Signs	Duration	Treatment	Results
1	1928	50	♀	LC	Frequency and burning not associated with cyst	1 yr	Nephrectomy	Cure

\* LC = central portion of left kidney. RC = central portion of right kidney. LLP = lower pole of left kidney. RLP = lower pole of right kidney. LUP = upper pole of left kidney. RUP = upper pole of right kidney.

They decide one's course of handling the condition. The wide open rather shallow diverticulum which is frequently seen situated to the left and to the right of the ureteral openings should not be treated. The question of the handling of the ureter in these cases is one of extreme importance. At operation it is well if one can, to identify the ureter before one operates by the passage of a ureteral catheter. The same thing holds true here as with panhysterectomy that one should get close to the pelvic wall and use an indwelling ureteral catheter to prevent damage to the ureter. It not only will do that but will in some cases furnish a clue as to whether the ureter will require treatment in the steps subsequent to diverticulectomy. Where the diverticulum has the ureteral opening in it, transplantation should be done. It is remarkable if this is done carefully and simply with not too much sewing and not too much stitching how sometimes one gets away apparently with murder.

DR T. LEON HOWARD, Denver. Delbert said that diverticula probably had their origin in the bud of a nondeveloped double ureter. Ward expressed the belief that they are congenital, with obstruction of the neck of the bladder. I have never seen a diverticulum without obstruction of the neck of the bladder whether in male or in female, and this obstruction

and was keeping up his pain, for it was over this area that he located his distress. A second operation was done immediately, and this diverticulum was exposed and opened and a permanent drain put in. This gave him permanent relief for at least a pint (475 cc) of serosanguineous fluid was released from a tense diverticular sac. I have encountered diverticula in the bladder in patients of all ages, both male and female but, as stated, have never seen one in which some form of obstruction at the neck of the bladder was not demonstrable. To remove a diverticulum without removing that obstruction, either previous to or at the time of the resection of the sac is only to court trouble and should never be done. Except in rare cases the obstructing cause should be removed first, and it is surprising in how many cases no further surgical measures will be required.

DR THOMAS E. GIBSON, San Francisco. Dr Fish deserves credit for presenting a practical contribution to the treatment of solitary cysts of the kidney, namely their cure by aspiration and injection of a sclerosing solution of 50 per cent dextrose. The members will all agree that this treatment should be reserved for those cases in which surgical intervention is not feasible. Operation obviates the danger not only of mistaken diagnosis but of overlooking possible associated malignant

growths either within the cyst or on the kidney itself. Another point of value which Dr Fish emphasized is that in most cases in which surgical measures are used simple excision of the free portion of the wall of the cyst and phenolization of the adherent portion are all that are necessary. Excision of the entire cyst cannot be performed without encroaching on a certain amount of adjacent parenchyma, which may involve troublesome bleeding and require control by mattress sutures. It is important to conserve all renal tissue possible, because the cyst itself may have destroyed from one half to three fourths of the kidney. Sometimes also the wall of the cyst approaches so close to a calyx that total excision may result in opening into it, thereby adding to the surgical problem, so the phenolization of the adjacent sac appeals to me as a good simple plan.

DR ROBERT V. DAY, Los Angeles. The fundamental thing in treatment of diverticula is to remove the obstruction at the neck of the bladder or, as happens occasionally, in the urethra. That is important. I think urologists are neglecting a lot of cases in which operation should be done. If they drain, the amount of drainage depends on the relative size of the cystic sac.

## THE TREATMENT OF PNEUMOCOCCIC INFECTIONS IN INFANTS AND CHILDREN WITH SULFAPYRIDINE

HENRY L. BARNETT, MD  
ALEXIS F. HARTMANN, MD  
ANNE M. PERLEY, MA  
AND  
MARY B. RUHOFF, AB  
ST. LOUIS

Whitby,<sup>1</sup> in May 1938, reported experiments showing that 2-(*p*-aminobenzenesulfonamido) pyridine (M & B 693, T 693, Dagenan, referred to in this report as sulfapyridine<sup>2</sup>) is chemotherapeutically active in experimental infections in mice against pneumococci of types I, II, III, V, VII, VIII and particularly against types I, VII and VIII, protecting against 10,000 lethal doses of type I. In Whitby's experience, it was the one compound observed to be effective against the pneumococcus in the assessment of more than sixty-four compounds related to sulfanilamide. He reported also that this drug is as effective as sulfanilamide against hemolytic streptococci and meningococci. This compound is a white, crystalline almost tasteless solid, soluble in water at ordinary temperatures to the extent of approximately one part in 1,000. It has the constitutional formula

From the formula, it will be

seen that the compound differs from sulfanilamide in that one hydrogen of the sulfamide group is replaced by a basic pyridine group. Wien<sup>3</sup> investigated the toxicity of sulfapyridine and determined that the average lethal dose for mice and rats was about four times that of sulfanilamide. He showed also that, in contrast

to sulfanilamide, which caused a large increase in the excretion of urinary porphyrin accompanied by a decrease in the red blood cell count and deposition of hemosiderin in the spleen,<sup>4</sup> this drug had no such effect on the hemopoietic system in causing a disturbance in pigment metabolism, even when given in twice and four times the dose of sulfanilamide. He concluded from his observations that this drug was much less toxic than sulfanilamide. Fleming<sup>5</sup> confirmed Whitby's observations in regard to the effectiveness of the drug against pneumococci and hemolytic streptococci. Maegraith and Vollum,<sup>6</sup> in *in vitro* experiments, found the drug to be an efficient bacteriostatic agent against *Streptococcus viridans* in dilutions up to 1 in 60,000, whereas sulfanilamide and "Soluseptazine" were ineffective in dilutions above 1 in 2,000. They reported also the effectiveness of the drug *in vitro* against meningococci and gonococci.

In June 1938, Telling and Oliver<sup>7</sup> reported recovery in a case of massive pneumonia, type III, with massive collapse, treated with the drug. In July 1938, Evans and Gaisford<sup>8</sup> reported 100 cases of lobar pneumonia in which the drug was used and 100 control cases, alternate hospital admissions being chosen for the treated group. By comparison of the temperature curves, the clinical courses, and the mortality rates in the two groups, they concluded that the drug had a definite beneficial effect on the course of the disease. They reported also the use of the drug in forty cases of bronchopneumonia in children. Many clinical reports concerning the use of the drug in pneumonia have appeared in the British literature<sup>9</sup> following these earlier experimental and clinical papers on the use of the drug. Four recoveries from pneumococcal meningitis<sup>10</sup> are reported, as well as satisfactory results in the treatment of gonococcal ophthalmia,<sup>11</sup> gonorrhea,<sup>12</sup> pneumococcal septicemia,<sup>13</sup> staphylococcal septicemia,<sup>14</sup> chronic meningococcal septicemia,<sup>15</sup> intranasal furuncle<sup>16</sup> and pemphigus<sup>17</sup> and clinical improvement with

out cure in subacute bacterial endocarditis<sup>18</sup> At the time of this writing, the only report in the American literature of its use is that of Flippin and Pepper,<sup>19</sup> who reported favorable results in the treatment of four cases of lobar pneumonia in adults

Up to the present time we have treated twenty-three hospital patients with sulfapyridine Our reason for reporting on such a small number of cases is that our clinical and laboratory data are confirmatory of the observations and conclusions of the British workers referred to Our series includes fourteen cases of pneumonia, three of which were complicated by the presence of empyema, one being further complicated by purulent pericarditis, four cases of bronchitis, three cases of pneumococcic peritonitis, one case of influenzal meningitis, and one case of subacute bacterial endocarditis (*Streptococcus viridans*) The clinical pictures in each of these patients, with the exception of the two last mentioned, suggested the presence of pneumococcic infections Such an etiology was confirmed by culture in the cases of empyema and those of peritonitis but in only two cases of pneumonia The diagnosis of pneumonia in every case was confirmed by either x-ray or fluoroscopic examination

#### PROTOCOLS

Sulfapyridine was determined in the blood, urine and other biologic fluids by the method of Marshall<sup>20</sup> for the determination of sulfanilamide as modified by Marshall and Litchfield<sup>21</sup> Sulfapyridine replaced sulfanilamide in the standards Methemoglobin was determined by the spectroscopic method described by Wendel<sup>22</sup>

CASE 4—D C, a white boy, aged 5½ years, entered the hospital Nov 23, 1938, with the history of an earache beginning November 18 There were no associated symptoms, however, until the day of admittance, when the patient was found

56 hrs after last dose  
of drug

On December 1 the patient was given 12 Gm of sulfapyridine as an initial dose, followed by 0.6 Gm every four hours. Fifteen hours after the initial dose of the drug the temperature had risen to 40 C (104 F), but eight hours later it was 38 C (100.4 F), following which it soon became and remained normal. December 3 an x-ray film still showed complete opacity of the right lower lobe of the lung. Immediately after the fall in temperature, however, the patient showed general improvement, and December 6 the chest appeared clear on fluoroscopy. The drug was discontinued December 10, after which the temperature continued to be normal.

CASE 9—J. D., a white boy, aged 29 months, weighing 12.3 Kg, entered the hospital Dec. 3, 1938, with the history of earache four days before admittance. On the day before he was brought to the hospital fever, cough and dyspnea had rather suddenly developed. The day of admittance he had become considerably more prostrated. On admittance he was listless, dyspneic, slightly cyanotic and quite prostrated with

a temperature of 39.8 C (103.6 F). Examination revealed a perforation of the right ear drum and there were both physical and fluoroscopic signs of lobar pneumonia involving the right upper lobe. December 3 the patient was given two doses of 0.3 Gm of sulfapyridine four hours apart. He then received a single dose of 0.6 Gm, which was followed by 0.3 Gm every four hours. The temperature of 40.6 C (105 F), present when the first dose of the drug was given, fell to 37 C (98.6 F) twenty-six hours later. The patient continued to look quite toxic, however, and after the temperature had been normal for fourteen hours it again rose to 38.4 C (101.1 F) and remained between 38 C and 40 C (100.4 and 104 F) until December 7. December 5 a bilateral myringotomy was done and gram-positive, encapsulated diplococci were seen, but no organisms were recovered on culture. *Pneumococcus* type XIV had been recovered from the blood stream of R. D. (case 6), the brother of this patient. Throughout the period of temperature elevation subsequent to the initial fall the patient continued to appear pneumonic, and the physical signs persisted. December 7 the dosage of sulfapyridine was increased to 0.6 Gm every four hours, and six hours later the tempera-

ture, previously 39.4 C (102.9 F), was again normal for the first time since the initial fall. December 8 the temperature again rose sharply to 40.2 C (104.4 F), following which it became and remained normal, and the patient showed marked clinical improvement, and resolution of the pneumonic process occurred.

CASE 10—J. B., a white boy, aged 8 years, weighing 21.8 Kg, entered the hospital Dec. 13, 1938, with the history of a slight cold which developed December 9, with no associated symptoms, however, until December 11, at which time he began to complain of pain in the chest and headache. These symptoms were followed by a rise in temperature and dyspnea, and December 12 he had a severe chill. He became more dyspneic and finally became semistuporous and irrational. On admittance he looked acutely ill, with a temperature of 39.8 C (103.4 F), and showed marked prostration and moderate dyspnea. Physical and fluoroscopic signs of lobar pneumonia involving the right middle lobe were present. Culture of material taken from the larynx by direct laryngoscopy on the night of admittance grew *pneumococcus* type I. Blood cultures December 13 and 14 were sterile. An x-ray film of the chest taken December 14 showed complete opacity of the right upper lobe. On this day the patient was started on sulfa-

pyridine, receiving two doses of 12 Gm three hours apart, followed by 0.6 Gm every four hours. The temperature, which at the beginning of the treatment was 40.5 C (104.9 F) fell to 37.8 C (100 F) twenty-six hours after the initial dose had been given and remained normal after this time. With the fall in temperature there was rapid clinical improvement and prompt resolution of the pulmonary changes. A cutaneous test made with specific soluble substance of *pneumococcus* type I showed only a slight erythema. December 15 but there was a definitely positive reaction with wheal formation December 18.

During the first two days of drug therapy the patient exhibited rather marked mental symptoms with gross disorientation and restlessness, but these subsided although the drug was continued in the same dosage.

CASE 14—M. B., a white girl, aged 6 weeks, weighing 4.2 Kg, entered the hospital Dec. 4, 1938, with the history of rhinitis, cough and fever beginning December 2. December 4 there was progressively increasing dyspnea, and on the morning of admittance she had become cyanotic. On admittance she looked almost moribund. Cheyne-Stokes respiration was present, and the pulse was rapid and weak. The temperature was 38.4 C (101.1 F). There were fine rales throughout.

After methylene blue  
6

both lung fields. The right ear drum was full and bulging. The patient was placed in an oxygen tent immediately and given stimulants. A myringotomy was done, the smear from which showed gram-positive encapsulated diplococci, identified later on culture as *pneumococcus* type XIX. December 5 the patient was given an initial dose of 0.3 Gm of sulfapyridine, followed by 0.15 Gm every four hours. The temperature was

within normal limits when the drug was started and, except for a rise to 38.5 C (101.3 F) December 7, did not become elevated. By this day, the patient had shown marked improvement with clearing of the pulmonary condition. December 9 there was again very marked cyanosis, and the concentration of methemoglobin was found to be 32 per cent of the total pigment. The cyanosis almost completely disappeared shortly after the intravenous administration of methylene blue. The drug was discontinued December 13.

CASE 17—L. S., a white girl, aged 5 years, weighing 17 Kg., entered the hospital Nov. 13, 1938, with a history of fever and vomiting since November 3, associated with cough and rapid respirations since November 6. There had been no period of clinical improvement during the course of the illness. On admittance the patient was acutely ill, with a temperature of 40 C (104 F). There was marked dyspnea and some cyanosis, and there were physical and fluoroscopic signs of lobar pneumonia involving the right upper lobe. The patient was given 12 Gm of sulfapyridine four hours after admittance, followed by 0.6 Gm every four hours. After four hours the temperature was 37.6 C (99.7 F) and four hours later 37.2 C (99 F), and the patient showed marked clinical improvement. There was then an elevation of the temperature to 38.6 C (101.5 F) during the next twelve hours, following which it became and remained normal until November 21. The drug was continued in the same dosage until November 18, at which time it was discontinued. During the period of administration of the drug the patient appeared clinically much improved, although the physical signs in the chest persisted. November 21 there were physical and x-ray signs indicating encapsulated accumulation of fluid, and on thoracentesis 60 cc of thick fluid was obtained, the culture from which showed pneumococcus type I. On this day, three days after the drug had been discontinued, elevation of the temperature again occurred, and the patient began to have daily spikes up to 39.4 C (102.9 F). November 25 sulfapyridine was again started in dosage of 0.6 Gm every four hours. The next day thoracostomy with

CASE 18—H. R., a white boy, aged 10 years, weighing 24.4 Kg., entered the hospital Nov. 23, 1938, with the history of an illness diagnosed as lobar pneumonia which began eighteen days before admittance. The symptoms had continued for twelve days, following which the temperature was normal for five days and the patient somewhat improved. The cough, however, continued, and he still appeared ill. On the day of admittance the temperature rose to 38.9 C, the cough became

more severe and he seemed generally worse. On admittance he looked moderately ill. The temperature was 39 C (102.2 F), the pulse 120 and the respiratory rate 36. Physical examination and fluoroscopy revealed the presence of unresolved pneumonia in the left upper lobe of the lung and a greatly enlarged pear-shaped heart shadow. A pericardial tap was made soon after admittance, and thick pus was obtained which on direct smear showed gram-positive encapsulated diplococci, the culture from which was later reported as sterile. Immediately after the diagnostic pericardial tap the patient was given 0.6 Gm of sulfapyridine, which was followed by 0.6 Gm every four hours and was continued until November 24, on which day operation was done for drainage of the pericardial empyema. Pus was obtained at operation, the culture from which was reported as pneumococcus type I. The temperature of 39 C on admittance and at the time the drug was started had fallen to 37.5 C (99.5 F) twenty hours later, at which time the operation was done. The drug was started again November 25 and the patient received 0.6 Gm every four hours until December 8. On the first day after operation the temperature rose to 38.6 C (101.5 F), after which it became and remained within normal limits until December 4, and then daily spikes to 39.5 C (103 F) occurred for two days. Following this, the temperature again became normal and the patient showed marked clinical improvement.

During a period of six days, beginning two days after administration of the drug was started, he excreted in the urine from 1.7 to 2.5 Gm a day, with a total of 12.1 Gm during which time he received a total of 21.6 Gm of sulfapyridine (3.6 Gm daily). The excretion during the period amounted to 56 per cent of the quantity administered. From 51 to 61 per cent of the drug appearing in the urine was present in the free form.

CASE 19—D. R., a white boy, aged 3 years, weighing 16 Kg., entered the hospital Oct. 22, 1938, with the history of puffiness of the eyelids first noticed eight weeks before admittance, associated during the two weeks prior to admittance with swelling of the abdomen, edema of the ankles and decreased urinary output. There had been no known preceding infection, and the patient had eaten and felt well throughout the course of the illness. Examination on admittance revealed no evidence of active infection, there was generalized edema with ascites. The urine contained much protein many red blood cells, white blood cells and casts. The blood showed no retention of nitrogen but markedly lowered serum protein values, particularly the albumin fraction, and the patient was considered to be in the chronic active stage of glomerulonephritis with nephrotic tendency. There was no hypertension. For the first eight days in the hospital the patient gained weight slowly and began to eat poorly. Because of the gradually increasing ascites

drainage of the empyema was done. The temperature rose sharply again on the following day and then became and remained normal. The drug was continued in the foregoing dosage until December 7 and then was again discontinued, and the patient appeared practically well.

During a period of four days, beginning four days after administration of the drug was resumed she excreted in the urine from 1.6 to 2.4 Gm a day, with a total of 7.8 Gm of sulfapyridine during which time she received 14.4 Gm (3.6 Gm a day), the excretion amounting to 54 per cent of that administered. From 61 to 71 per cent of the drug appearing in the urine was present in the free form.

abdominal paracentesis was done October 30 and 250 cc of clear fluid was removed which contained no cells and the culture from which was reported as no growth. The following day, October 31, the patient began to complain of abdominal pain, and the temperature, previously normal, rose to 39 C (102.2 F) and four hours later to 40.3 C (104.5 F). An abdominal paracentesis was immediately done, which yielded cloudy fluid containing many polymorphonuclear cells, the culture from which on the

following day showed type XV pneumococci. A blood culture taken at this time also grew type XV pneumococcus. Although no organisms could be seen on smear at the time of the paracentesis, two hours after the elevation of temperature the patient was started on sulfapyridine, being given 0.6 Gm as an initial dose, followed by 0.3 Gm every three hours. Six hours after the initial dose the temperature had fallen to 38.4 C (101.1 F) and eight hours later was 37.6 C (99.7 F). Culture of material taken from the throat the day of onset showed a pneumococcus which was not of the same type as that recovered from the ascitic fluid and blood. Cultures of the blood and ascitic fluid on November 1 were again reported as positive for type XV pneumococci. On this day the dose of the drug was increased to 0.3 Gm every two hours (0.22 Gm per kilogram in twenty-four hours). During the day the temperature rose to 38.6 C (101.5 F) for a period of twelve hours, following which it became and remained normal. The patient showed marked clinical improvement within fourteen hours after the drug had been started. The blood and ascitic fluid were both sterile November 2 and 3, on the latter day the ascitic fluid being again clear.

CASE 20—F F, a white girl, aged 6 years, weighing 24.2 Kg, entered the hospital Dec 2, 1938, with the history of having been well until November 22, at which time puffiness of the lids was noted. This was followed by gradually increasing generalized edema, with ascites also, during the last three days preceding admittance. The urinary output had been decreased

Twelve hours before admittance the temperature had been taken and was said to have been normal. On admittance the patient, while not acutely ill, had a temperature of 38.8 C (101.8 F). Generalized edema, moderate injection of the tonsils and posterior pharynx and tenderness over the right kidney region were noted. The urine contained much protein occasional red blood cells, white blood cells and many casts. There was no hypertension. Serum proteins were markedly decreased, particularly the albumin fraction, there was no retention of nitrogen. Fifteen

hours after admittance the temperature had risen to 39.8 C (103.6 F) and a blotchy, morbilliform rash was noted over the right side of the abdomen, with cutaneous hyperesthesia and some deep abdominal tenderness. At this time an abdominal paracentesis was done, which yielded 100 cc of grossly clouded fluid, which contained leukocytes and from which pneumococcus type XXIII was recovered on culture. Cultures of material from the nose, throat and blood stream all yielded the same organism. Immediately after the paracentesis sulfapyridine was given in doses of 1.2 Gm at two hour intervals for the first three doses, followed by 0.6 Gm every four hours for four doses, after which it was increased to 1.2 Gm every four hours. During the first twenty-four hours after the initial dose the temperature remained markedly elevated, and the patient appeared acutely ill and toxic. There was severe abdominal pain. The pulse rate was very rapid and the quality poor. An erysipeloid eruption appeared on the abdomen and spread down to the thighs. After twenty-four hours the patient was given 100,000 units of broad coverage (DRI) antipneumococcus rabbit serum, and on the following day an additional 60,000 units was given. The patient received blood transfusions also on these days. The temperature remained elevated and the child remained critically ill until December 5, at which time the temperature became normal and she seemed somewhat improved. The temperature remained within normal limits after the fall December 5, on which day the dosage of the drug was reduced to 0.6 Gm every four hours. December 6 the patient began to have marked distention with severe vomiting and gastric distress. These symptoms were relieved by continuous duodenal suction, and she then showed marked clinical improvement. While the large doses of the drug were being given cyanosis developed, which disappeared with the intravenous administration of methylene blue.

CASE 21—D V, a white girl, aged 10 years, weighing 30 Kg, entered the hospital Dec 7, 1938, with the history of having had abdominal pain for four days. She went to school December 5,

#### Blood in Case 21

but that evening the pain became more severe, she had begun to have fever, and there was some nausea. December 6 she became definitely worse, first vomiting and then severe diarrhea developed. On admittance she appeared very ill, she was quite toxic and dehydrated, with a temperature of 40 C (104 F) and a pulse rate of 160. There was tenderness in the lower part of the abdomen and some resistance, and exquisite tenderness was elicited on rectal examination. She was given fluids parenterally and on the following morning, December 8, appeared generally better, but the abdominal tenderness had become more marked, there was also definite rigidity of the lower part of the abdomen, more marked on the right side. An exploratory laparotomy was done, at which time peritonitis was found with a large amount of thick pus in the pelvis. This was evacuated and the appendix, which was found to be intact, was removed. Smear of the pus revealed gram positive encapsulated diplococci. On this day a blood culture taken the day previously was reported positive for pneumococcus type I, this organism was also recovered from pus obtained at operation. December 8, immediately following operation, the patient was given three doses of 1.8 Gm each of sulfapyridine in a period of seven hours, followed by 0.9 Gm every four hours. The temperature of 40.6 C (105.1 F) at the time the drug was started fell to 37.8 C (100 F) eleven hours later and after a single rise on the following day to 38.5 C (101.3 F) became normal. The signs of toxicity were greatly alleviated after the fall in temperature, the abdomen became soft with but very slight tenderness, and the amount of drain age from the wound rapidly diminished during the next five days. The drug was discontinued December 13, at which time

the patient appeared quite well. The temperature remained normal until the evening of December 15, at which time it again became elevated and ranged between 37 C and 39 C (98.6 and 102.2 F) until December 20, when it rose to 40.6 C. During this time the patient continued to feel fairly well, but December 18 she complained of some abdominal cramping, and a rectal examination at this time revealed a large, tender mass in the culdesac. December 20 the patient was again given sulfapyridine, starting with an initial dose of 18 Gm, followed by 0.9 Gm every four hours. December 21 the temperature continued to remain elevated, and incision and drainage of the culdesac abscess through the vagina was done, approximately 500 cc of pus being obtained, the culture from which grew pneumococcus type I.

CASE 22—P. H., a white girl, aged 11 years, weighing 23.6 Kg, who was known to have subacute bacterial endocarditis, reentered the hospital Dec. 9, 1938, for sulfapyridine therapy. She had first been seen by us July 11, 1938, at which time she gave a history of having had intermittent attacks of migratory polyarthritides and palpitation and dyspnea on exertion for five years and anorexia with loss of weight and strength for three months. On physical examination at that time the child was moderately emaciated, thin and pale and looked chronically ill. The outstanding physical changes were a markedly enlarged heart with signs of advanced mitral stenosis and an enlarged spleen, palpable 3 cm below the left costal margin. During that hospital stay she had an intermittent fever (37-39 C or 98.6-102.2 F). Blood cultures taken July 12, 14, 17, 19 and 22 all

grew *Streptococcus viridans*. The patient was discharged July 22 as unimproved, with the diagnosis of subacute bacterial endocarditis engrafted on a rheumatic heart lesion. During the interval between this discharge and the present admission the patient had had intermittent periods of elevation of temperature up to 39 C (102.2 F), which usually lasted for from six to seven days, following which she was apparently afebrile for from seven to ten days, although the periods and intervals occurred with no definite regularity. During the periods of elevation of temperature the patient ate poorly, had considerable malaise and remained inactive. During the intervals also her appetite was also poor, but she enjoyed a certain amount of limited activity, which included short walks and automobile rides. At no time had she been completely bedridden. The patient had had two mild attacks of joint pains. She had lost 4 pounds (1.8 Kg). On the present admission she presented a picture similar to that already described but appeared more emaciated. During the first six days in the hospital she had regular daily elevations of temperature to 39 C, the temperature becoming normal between the spikes. Blood cultures December 9, 11, 13 and 14 were all positive for *Streptococcus viridans*. Those taken December 10 and 12 yielded *Staphylococcus aureus*, which was believed to be a contaminant, since the organism did not ferment mannite. December 15, at 10:30 a.m., the patient was given 18 Gm of sulfapyridine, followed by 18 Gm at 12 noon and 0.9 Gm every four hours beginning at 2 p.m. The blood culture taken at 4:30 p.m. December 15 and daily blood cultures taken until December 21 have all been sterile. During this time there has been no elevation of the temperature, and, except for some mild nausea and vomiting during the first twenty-four hours of treatment, the patient has felt and appeared definitely improved generally. December 18 the dosage of the drug was decreased from 0.9 to 0.6 Gm every four hours.

CASE 23—H. G., a white boy, aged 10 months, weighing 8.6 Kg, entered the hospital Aug. 28, 1938, with the history of stupor and fever of four days duration. The diagnosis of influenza meningitis was established at this time, and during the next fifty-two days the patient was treated with anti-

influenza serum, sulfanilamide and prontosil (the disodium salt of 4-sulfamido-phenyl-2'-azo-7'-acetyl-amino-1'-hydroxynaphthalene-3',6'-disulfonic acid), given by all suitable routes until the time at which sulfapyridine was tried. The patient throughout this time had shown several periods of improvement, but the cultures of the spinal fluid still showed growths of *Haemophilus influenzae*. October 18 the patient was given 0.6 Gm of sulfa-

pyridine as an initial dose, followed by 0.3 Gm every four hours. This dosage was continued for sixteen days until November 2, during which time the patient received a total of 30 Gm of the drug. There was no demonstrable effect of the drug on the clinical course of the disease or on the bacteriologic picture.

#### COMMENT

As soon as we were assured of an adequate and uninterrupted supply of sulfapyridine for investigative purposes it seemed best to us for several reasons to attempt no selection of cases but instead to treat with the drug as soon as possible without waiting for reports on cultures all cases of infections of the lower part of the respiratory tract, on the assumption that most of them would prove to be pneumococcal in origin. The almost certain advantages of early treatment would in this way not be denied any patient, and

Chart 1—Relationship of fall in temperature to administration of sulfapyridine in cases of pneumonia

for this reason also it was decided not to attempt to secure a "control" group of untreated cases, as might have been done if, for instance, we had selected for treatment only alternate cases. We were anxious also to observe the effects of treatment in as many cases as possible throughout the entire winter season to note whether any substantial difference in response occurred

as the winter progressed and the incidence and severity of "secondary" pneumonias increased. The fact that St Louis was one of the cities selected by the U S Public Health Service for the study of type incidence and serum (horse) therapy and that a special study of the value of immune rabbit serum therapy was being conducted simultaneously by the Department of Internal Medicine of the Washington University School of Medicine also contributed to our decision to confine our study largely to sulfapyridine. At a later date, therefore, we should be able to compare results of different methods of treatment of essentially similar infections. Our observations in this preliminary report should be considered only as indicative of what might be expected from this new drug.

CLINICAL RESULTS

**Uncomplicated Pneumonia**—The difficulty in demonstrating the efficacy of any therapeutic agent in primary pneumonia of the lobar type is apparent. The low mortality of this disease in children, usually quoted as from 3 to 5 per cent, is well known, and other criteria by which types of therapy can be judged are difficult to evaluate. The temperature curves of the patients treated with the drug are shown in chart 1. The possibility cannot be eliminated that the dramatic fall in temperature, which, as can be seen, has occurred in every case of pneumonia thus far coming under treatment with the drug within twenty-eight hours after the initial dose, might have been due to a spontaneous crisis. Each one has occurred at a time when a spontaneous crisis might have been expected, and it is certainly not unusual for the crisis to occur within the first twenty-four hours after the patient enters the hospital, since the increased toxicity developing prior to the crisis is often the very reason that the patient is brought to the hospital. Nevertheless, a mere inspection of statistics relative to the day of crisis in lobar pneumonia<sup>23</sup> would make it most unexpected even in only eleven cases for this to occur so regularly, and if it is found to occur in a much larger number of cases more substantial importance may be attributed to it. Evans and Gaisford state

Chart 2—Relationship of fall in temperature to administration of sulfapyridine in cases of bronchitis

that in adults the clinical improvement after the fall in temperature in patients treated with the drug is more gradual than in those in whom a spontaneous crisis occurs, but in our experience the fall in temperature is followed by as rapid clinical improvement as we are accustomed to see in untreated cases. In only one case did the temperature again become elevated after the initial fall during the time that administration of the

drug was continued. In this case (case 9) both the physical signs and the clinical appearance of the patient suggested a continuation of the pneumonic process and were quite typical of pneumococcic lobar pneumonia, although the organism responsible for the infection was not recovered. It may be that we were dealing with a type of pneumococcus less susceptible to the action of the drug, although type XIV pneumococcus was cul-

Chart 3 (case 19)—Recovery from pneumococcic septicemia and peritonitis with sulfapyridine alone

tured from the blood stream of the brother of this patient, who was in the hospital at the same time and whose course was similar to those of the other patients treated. Another possibility which suggests itself from the blood concentrations of the drug is that the dosage was inadequate, since the initial fall in temperature occurred when the blood concentration was 9 mg per hundred cubic centimeters, the blood concentration during the later rise of temperature being 53 and 20 mg, the second fall in temperature occurred promptly after the dosage was increased.

**Pneumonia with Empyema**—Two of the cases of pneumonia which were complicated by empyema are particularly interesting in regard to the bacteriologic data obtained. Both of these were due to type I pneumococcus, and in both there were signs of the presence of empyema before the drug therapy was started. In case 16, particularly, it was interesting that, in spite of the fall in temperature, the decreased toxicity and the general improvement of the patient, the collection of fluid in the pleural cavity seemed to continue unabated, the fluid appeared to thicken more slowly than usual and the cultures from it remained positive, as did those also in case 17. Resections of ribs with open drainage of the empyema were done in both cases, and the patients made uneventful recoveries.

**Pneumonia with Pericarditis**—This was also due to the type I pneumococcus. The clinical course of the case was satisfactory, but the role of the drug therapy was difficult to evaluate.

**Bronchitis**—Four cases of bronchitis were selected for sulfapyridine therapy because of the probability of their being due to a pneumococcic infection either (as in case 13) because of contact with a case of lobar pneumonia or (as in the case of M. B.) because of the presence of otitis media from the pus in which pneumococci were recovered on culture. The fall in

23 Holt L. E. Jr and McIntosh Rustin. *Holt's Diseases of Infancy and Childhood*, ed 10. New York: D. Appleton Century Company, 1936, p. 429.

temperature shown in chart 2 and the clinical improvement were quite striking in each of the four cases

**Pneumococcic Peritonitis**—This type of pneumococcic infection, next to that of meningitis, lends itself the most easily to the evaluation of a type of therapy. Particularly when it occurs in patients with active nephrosis or chronic nephritis with marked nephrotic tendency, in which cases it is so common and so often fatal, it can very readily be diagnosed by abdominal paracentesis, treatment may be instituted early and the course of the disease followed bacteriologically by subsequent abdominal paracenteses. In the two cases of this sort that we have treated, 19 with sulfapyridine alone and 20 by a combination of the drug and antipneumococcus rabbit serum—the results were very satisfactory. The control of the infection in the first patient, as contrasted to the usual stormy course that these children have if they do survive, is most striking. No less so is the clinical course of patient 21, who

Chart 4 (case 20)—Recovery from pneumococcic septicemia and peritonitis with sulfapyridine plus antipneumococcus rabbit serum

had a primary pneumococcic peritonitis with septicemia. Charts 3, 4 and 5 show the essential observations made in these three cases

**Subacute Bacterial Endocarditis (*Streptococcus Viridans*)**—The results thus far obtained in the single case of this disease which we are treating are shown in chart 6. The immediate cessation of the rises in temperature with sterilization of the blood stream are confirmatory of the results obtained by Whitby,<sup>18</sup> who observed also that the fever recurred when drug therapy was discontinued and could again be promptly controlled on resumption of administration of the drug. With these two objective indications of the effectiveness of the drug, the patient has shown apparent improvement in her general condition. The effect of sulfapyridine in this disease, in our experience, is in marked contrast to that of sulfanilamide, with the use of which, in three cases, we were unable to find any indication of improvement even when very large doses were given and the blood concentration maintained at a level as high as 50 mg per hundred cubic centimeters.

**Influenzal Meningitis**—In the single case of this disease in which we have given sulfapyridine, no effect was observed on either the clinical course of the disease or the bacteriologic changes. The drug had no effect on the fever in this case.

# TOXICITY

Concerning the toxicity of the compound, Wien's<sup>9</sup> studies in the lower animals already have been mentioned. Whitby states that in his clinical experience he has as yet observed no more serious toxic effects than cyanosis, nausea and sometimes troublesome vomiting, of which the last is a particular disadvantage because the low solubility of the drug would seem to

Chart 5 (case 21)—Recovery from pneumococcic septicemia and peritonitis with sulfapyridine alone

preclude the possibility of adequate parenteral administration. Whitby feels that the vomiting is not of central origin. Lloyd, Erskine and Johnson<sup>24</sup> believe that clinically the toxic results are comparable to those of sulfanilamide, given in equal amounts, but that lower doses of sulfapyridine are effective. To the toxic manifestations mentioned by Whitby, they add the occur-

Chart 6 (case 22)—Remission of bacteremia and fever induced by sulfapyridine in case of *Streptococcus viridans* subacute bacterial endocarditis

rence of cutaneous rashes in six out of 108 cases, and the occurrence of headache, dizziness, fainting or depression in ten of the 108 cases. Other investigators,<sup>25</sup> however, agree with Whitby that clinically the toxic results are few and definitely less marked than

24 Lloyd V E, Erskine, D and Johnson A G. Chemotherapy of Gonorrhea with M & B 693. *Lancet* 2: 1160-1163 (Nov. 19) 1938.  
25 Duke and Reid. *Prebble* 12.

those due to sulfanilamide. Nausea and vomiting, which could be directly attributed to the drug, have not seriously complicated its use in any of our patients thus far treated. As is true with sulfanilamide, such toxic effects as these may be less prominent in children than in adults. As in the case of sulfanilamide therapy, cyanosis due to the accumulation of methemoglobin occurs quite frequently during the administration of sulfapyridine and may be prevented or controlled by the use of methylene blue.<sup>26</sup> This becomes of more clinical significance in cases of pneumonia, since it is of importance to determine whether existing cyanosis is of pulmonary or of cardiac origin or due merely to unnecessary and controllable excessive methemoglobinemia. The possibility of the development of a large amount of methemoglobin is particularly demonstrated by M. D., who was quite cyanotic on admittance to the hospital because of extensive capillary bronchitis. This cyanosis was relieved when the patient was put into an oxygen tent, but several days later, after the patient had been receiving sulfapyridine, and when otherwise she seemed greatly improved, an intense cyanosis was again noted. Her methemoglobin concentration at this time was 32 per cent of the total pigment, and after methylene blue was given intravenously the cyanosis disappeared and her color became in accord with her general improved clinical condition. Mental confusion, similar to that occurring during the administration of sulfanilamide, has been noted in several patients receiving sulfapyridine. As can be seen from the protocols, in no instance has there occurred a fall in the red blood cell count which could be attributed directly to the drug. In one case of empyema and in one case of peritonitis anemias developed which required transfusions, but the anemias were not severe, were easily controlled and were no more striking than the fall in the red blood cell count which so often occurs in any severe infection. In the other cases, even in those

The data that we have obtained concerning the absorption and excretion are presented in the protocols. The highest blood concentration of the free form of the drug observed with the dosages which we have employed is 15.9 mg per hundred cubic centimeters, the concentrations more often ranging between 5 and 10 mg. Besides the quantity of the drug administered, other factors will influence its concentration in the blood, particularly the fluid intake and output and any factors interfering with absorption from the gastrointestinal tract. As can be seen from the protocols, in several instances traces of the drug were detected in the blood as long as forty-eight hours after administration of the drug had been discontinued. In the single case

TABLE 2—Sulfapyridine Dosages for Infants and Children

Age	13 mos	6 mos	1 yr	2 yrs	3 yrs	12 yrs
Dosage	0.15 Gm every 4 hours	0.3 Gm every 4 hours	0.3 Gm every 3 hours	0.6 Gm every 4 hours	0.9 Gm every 4 hours	0.9 Gm every 4 hours

of meningitis in which this treatment was given, the data suggest that the concentration in the spinal fluid is roughly about 60 per cent of that in the blood, which may mean only that changes in the spinal fluid concentration may lag behind those in the blood. Cunningham,<sup>27</sup> however, reports that he found the concentration of the drug in the spinal fluid to be only about one half that of the concentration in the blood in contrast to the more even distribution of sulfanilamide. In the cases that we have studied the concentration in empyema fluid was as great as and in most instances somewhat greater than that obtained simultaneously in the blood. It is interesting to note that in case 17 sixty hours after administration of the drug had been discontinued, and at a time when the blood showed only a trace of the drug, the chest fluid still contained 2 mg per hundred cubic centimeters.

With a constant intake of the drug, the percentage recovered in the urine from three patients in whom complete twenty-four hour urine specimens were obtained over periods of several days ranged from 54 to 59 as shown in the protocols. The fraction of the drug in the urine presumed to be the free form, since it can be determined colorimetrically without preliminary hydrolysis, as can be seen from table 1, varies considerably in a given person, but some persons tend rather consistently to conjugate a relatively larger proportion than others.

## DOSAGE

In adults, Whitby<sup>18</sup> recommends giving 5 Gm in the first twelve hours in lots of 2 Gm, 2 Gm and 1 Gm, at intervals of four hours, followed by 1 Gm every four hours. The approximate doses of the drug which we have employed are as indicated in table 2 and are approximately those recommended by Evans and Gaisford<sup>8</sup> for children. We have in all cases given at least a single initial double dose. In certain severe known pneumococcic infections, as can be seen from the protocols, the usual dosage has been increased. Because of the relative insolubility of the drug, all our patients have been treated by oral administration only. So far, we have administered the drug in powder form suspending it in water, milk or fruit juices. When vomiting was present, mixing the drug with apple sauce or a small amount of jelly proved helpful.

TABLE 1—Ratio Free Total Sulfapyridine in Urine

Case	Range per Cent	Average per Cent
5	9.34	17
7	40.56	47
8	47.72	57
10	48.54	51
16	42.68	57

20	42.72	58
21	37.79	53
22	54.56	55

in which rather large amounts of the drug were given over considerable periods of time, no tendency toward anemia was noted.

## ABSORPTION AND EXCRETION

According to Whitby,<sup>18</sup> sulfapyridine despite its relative insolubility, is readily absorbed, even more rapidly than sulfanilamide, and it is excreted somewhat more slowly. He states that after the initial dose has been given and followed by administration at intervals of four hours, the maximum blood concentration is obtained in about twelve hours. He states also that the blood contains no drug twenty-four hours after treatment has ceased but the urine contains traces for some forty-eight hours. According to his data, the drug is excreted in about equal proportions of free and conjugated forms.

## SUMMARY AND CONCLUSIONS

1 The clinical results were observed in the treatment of twenty-three infants and children with sulfapyridine [2-(*p*-aminobenzenesulfonamido) pyridine]. These patients included fourteen with pneumonia, three with empyema, four with bronchitis, three with pneumococcal peritonitis, one with influenzal meningitis and one with subacute bacterial endocarditis. Despite the small number of patients treated, our results, confirmatory of the reports concerning the use of the drug in adults, are encouraging and should prompt its early use, particularly in suspected pneumococcal infections. If definite improvement should not occur in twenty-four to thirty-six hours, specific serum therapy, if available, should be instituted if the clinical condition indicates its use.

2 The toxic symptoms encountered following the administration of the drug were mild nausea, vomiting and slight mental confusion, all of which usually subsided even with continued administration of the drug and none of which were ever sufficiently severe to interfere with the treatment.

3 Cyanosis due to the accumulation of methemoglobin was encountered in most of the intensively treated cases and was readily controlled by the use of methylene blue.

## ADDENDUM

Since submitting this report, we have treated fifty-seven additional cases with sulfapyridine. These have included twenty-six cases of pneumonia, seven cases of bronchitis, four cases of meningitis, two cases of peritonitis and seventeen miscellaneous cases. Except for three fatal cases (two of these patients were infants with bronchopneumonia not proved of pneumococcal origin and one older child with lobar pneumonia complicated by severe laryngotracheitis and dying twelve hours after treatment was begun) the pneumonias have had courses very similar to those described, as have had the cases of bronchitis. The types of pneumococci isolated in these cases were I, IV, VI, XI and XIV. Two patients with pneumococcal meningitis, proved by culture, were treated. One of these, whose spinal fluid teemed with organisms (type V pneumococcus), recovered. The second patient, with meningitis due to a type XIV pneumococcus, died sixteen hours after the drug therapy was started. A third patient with purulent meningitis, believed to be pneumococcal from examination of a stained smear but unproved by culture, was treated successfully. A second patient with influenzal meningitis was treated without demonstrable effect. The miscellaneous group in which the drug was used comprised a variety of cases, including staphylococcal infections, dysenteries and one case of tuberculous meningitis. No beneficial effects from the drug were observed in the treatment of these cases.

We have recently taken advantage of the greater solubility of the sodium salt of sulfapyridine, the preparation of which was described by Marshall and his co-workers,<sup>28</sup> by administering the drug in this form in a 2 per cent solution by rectum. By this method rapid absorption occurs, and we have also been able to maintain adequate blood concentrations. From observations made thus far, we are hopeful that nausea and vomiting due to the drug can in this way be largely prevented. We feel that this method of administration may prove quite helpful when vomiting from any cause prevents adequate oral administration.

<sup>28</sup> Marshall E K Jr, Bratton A C and Litchfield J T Jr. The Toxicity and Absorption of 2 Sulfanilamidopyridine and Its Soluble Sodium Salt. *Science* 88: 597-599 (Dec 23) 1938.

Two cases of agranulocytosis occurring during the administration of sulfapyridine have been reported in the British literature.<sup>29</sup> In case 21 of our series, three days after the drug had been discontinued for the second time the patient had a white blood cell count of 1,700. She developed a severe angina, and despite blood transfusions and other forms of treatment the white blood cell count continued to fall during the next four days, when it was counted as 75 cells per cubic millimeter with complete agranulocytosis. Two days following, the count began to rise, and continued to do so, reaching 22,500 on Jan 16, 1939. During this time, however, the patient developed extensive neck abscesses and a septic pneumonia, and on January 17 she had a sudden and fatal hemorrhage from the pharynx and the side of the neck where previous drainage had been instituted. This patient received a total of 80.9 Gm of sulfapyridine during seventeen days over a twenty-six day period. She was to all appearances well over her original infection several days before the agranulocytosis became manifest.

THE TREATMENT OF VENEREAL  
LYMPHOGRANULOMA WITH  
SULFANILAMIDE

ALVA A KNIGHT, M D

AND

VERNON C DAVID, M D

CHICAGO

Our experience in the treatment of venereal lymphogranuloma has been largely in the management of rectal strictures, although we have had under our observation and care lesions involving the soft parts, the floor of the mouth and the colon. The literature<sup>1</sup> lists many methods of treatment including administration of quinine, iodides, emetine, preparations of antimony, arsenicals, methylene blue, copper ammonium sulfate and chiniofon, inoculation with vaccines from the pus from buboes, x-ray and radium therapy, injections of tuberculin, of milks, of Frei antigen and of glycerin, and many others. Surgery was formerly advocated for removal of the infected glands and for radical removal of the rectum, but recurrence was the rule. Dilatation of the rectal stricture has not resulted in permanent relief. Colostomy for the rectal stricture has given the most outstanding relief, though the disease itself is not cured.

We have used many of these therapeutic measures on a large group of rectal strictures resulting from

venereal lymphogranuloma but have had no especial success with any of them. The most helpful in our hands have been colostomy and the intravenous use of antimony and potassium tartrate or the subcutaneous use of fuadin. Neither of these methods, however, has been curative, and we had reached a rather fatalistic attitude toward the clinical cure of the disease until our experience with sulfanilamide, which we believe should be given a thorough trial in all recognized lesions of this disease. The following reports are the basis for our enthusiastic advocacy of sulfanilamide.

G F, a man, came to Dr Knight Dec 8 1934, with a small anal ulcer and slight enlargement of the right inguinal gland. He entered Presbyterian Hospital December 26, at which time the anal canal was dilated by Dr Bevan, disclosing a large, flat, comparatively clean ulcer 8 mm in diameter situated on the anterior anal wall just inside the mucocutaneous line. After the anal sphincter was dilated an iodoform pack was inserted. The patient was discharged December 31 with the ulcer healing slowly.

He was seen Jan 4, 1935, in the office, at which time the anal ulcer was almost completely healed, but the right and left inguinal glands were moderately enlarged and hard but not tender. A digital examination of the rectum disclosed suggestive firm nodules along the left seminal vesicle.

The Wassermann reaction was negative. The tuberculin test was negative. Roentgenograms of the chest were negative, the Frei test gave positive results. The temperature was 99.4 F, white blood cells numbered 20,000 and the differential count was within normal range. The Frei test was rechecked with the antigen of the patient against a proved case of venereal lymphogranuloma. Intramuscular injections of fuadin were begun three times a week in doses of one ampule each and were continued without intermission until Aug 1, 1937, with the exception of a period of approximately three months, during which time Frei antigen was given intracutaneously twice a week. The patient continued to work throughout this period but remained thin and complained of easy fatigability and lack of pep and of a frequent desire to defecate. Stools during this period occurred from six to twelve times a day and contained much mucopurulent material.

Proctoscopic examinations were done on the average of once a month throughout this period. This revealed a gradually extending process regardless of treatment and resulting in gradual narrowing of this area with the maximum annular constriction occurring at a depth just reached with the tip of the index finger and barely admitting the tip of the finger through the constriction.

August 1, sulfanilamide was started in doses of 10 grains (0.65 Gm) the first day with an increase of 10 grains each day until a maximum of 60 grains (4 Gm) was reached, followed by a rest period of ten days, after which the course was repeated.

August 16, he wrote "I feel 100 per cent better and have a movement only twice a day." August 28, proctoscopic examination showed considerable improvement over the preceding examination. The sulfanilamide was continued on the basis of 30 grains the first day, 40 grains the second day, 50 grains the third day, 60 grains the fourth day, 50 grains the fifth day, 40 grains the sixth day and 30 grains the seventh day, with an interval of from ten days to two weeks between courses of treatment. Improvement continued until October 2, when a perianal abscess developed, which was drained by Dr David. The patient returned to work after two days with instructions to continue the sulfanilamide as previously outlined, except that the dose was to be increased until 90 grains was reached, after which it was to be stepped down as before. Frequent blood checks showed no disturbance in hemopoietic function.

Proctoscopic examinations at monthly intervals continued to show improvement until April 3, 1938. At this time the mucosa of the intestine appeared perfectly normal, the point of maximum stricture now admitting the passage of the proctoscope. The patient had gained 20 pounds (9 Kg) and stated that he had never felt better in his life. May 21 the fistulous tract was dissected out. The patient was discharged May 28 with

healing nearly completed. Healing progressed rapidly to completion. The patient has remained symptomatically well since that time. He was carefully examined in August, there was no induration in the mucosa, the stricture had disappeared and the fistulous tract was completely healed with continence of the sphincter.

At the same time at which this unusual result was achieved, we had in our service a most distressing case of progressive venereal lymphogranuloma in which the right ischio-rectal region, the scrotum and the adductor region of the right thigh were involved, with marked destruction of the soft parts and associated with profound constitutional effect.

A P, a white man aged 27, who entered our service at the Presbyterian Hospital Sept 18, 1936, had first noticed pain in the rectum, constipation and bleeding at the time of bowel movements in June 1936. A surgeon operated on the rectum (for fissure?) and thereafter he felt improved. He complained of pain in the right ischio-rectal fossa July 15 and a swelling developed which ruptured through the skin. This abscess was opened for further drainage. He then became violently ill with pain and elevated temperature and was taken to the hospital. An extensive incision was made in the right ischio-rectal fossa. Pain and induration had continued for the past six weeks.

When he entered the Presbyterian Hospital he was thin and in pain and had a slight elevation of temperature in the evening. There was no general adenopathy. The inguinal glands were not enlarged. The general examination was negative. The genitalia and the rectum were normal. The Wassermann reaction of the blood was negative. The blood pressure was 108 systolic, 70 diastolic. Examination of the urine was negative. The hemoglobin content was 87 per cent, red blood cells numbered 4,740,000, white blood cells 11,100. The bleeding time was sixty seconds and the coagulation time was thirty seconds. On the right ischio-rectal fossa there was a draining sinus leading into an open wound 4 inches (10 cm) long which was lined with pus-covered redundant granulation tissue. Posterior to the sinus was an abscess with marked induration over it. More as a matter of curiosity than anything else we had the Frei test made with three different antigens. They were all strongly positive.

October 12 fuadin 5 cc subcutaneously was given daily for ten days.

October 19 he was operated on and a sinus reaching anteriorly to the base of the scrotum was incised as well as one running laterally from the old incision. The lining of the old sinus was taken for microscopic examination. Acute chronic granulation tissue was reported.

Material from the wound was cultured on Herrold's medium for tubercle bacilli. There was no growth and smears from the pus showed no acid-fast organisms. Cultures showed no hemolytic streptococci. (A guinea pig was inoculated with the material November 1 and it died November 27. There were no lesions of tuberculosis.)

October 21, packs saturated with diluted solution of sodium hypochlorite were used in the wound because of marked necrosis in the depth of the wound, but without much avail. The temperature ranged from 99.4 to 101.8 F for ten days.

From November on he was given more injections of fuadin. By April 2, 1937, he had gained some strength and weight. The wound on the right buttock was swollen but by no means healed. There was undermining of the skin to the base of the scrotum with several discharging sinuses over it. The rectum was normal. The sinuses were again opened for better drainage and at the operation we decided to remove the lesion completely. The dissection was carried down to the gluteus muscles on the right, the fascia over it being removed. The lesion extended close to the intestine but did not involve it. Microscopic examination of the tissue removed showed chronic granulation tissue and fibrosis.

The patient left the hospital May 10 and returned September 13. The wound had remained open and was draining. An abscess cavity was found under the adductor muscles of the right thigh which connected with the abscess in the right ischio-rectal fossa. There was another abscess in the fold

between the right thigh and the scrotum. These abscesses were opened and to get adequate drainage it was necessary to divide some of the adductor muscles of the right thigh. The day after operation he lost about a pint of blood from hemorrhage from the wound. On September 18 he was given 115 grains (75 Gm) of arsphenamine, this dose was repeated September 27. On September 28 his temperature was 103 F, he was uncomfortable and was unable to sleep.

October 5 his general condition was about the same, but the suppurative process in the right ischio-rectal fossa extended deeply into the pelvis between the rami and the pubes and extended anteriorly into the adductor region and into the scrotum. (From November 8, roentgen therapy of the wound was carried out for ten days without apparent effect.) It was really a pitiable situation and the family was informed that we had carried out all the measures we could think of to help the situation, without avail. Zinc peroxide was used in the wound in the form of powder without apparent effect. At the lowest hour in the course of this particular lesion the report of the remarkable improvement of the first patient reached us, and we immediately began the use of sulfanilamide as outlined in the accompanying table.

At the time this treatment was started the wound was suppurating freely and extending, and the general condition of the patient was gradually getting worse. He was getting sedatives day and night.

By December 8 he no longer needed sedatives. The wound was covered with red granulation tissue. The discharge was serous and was increased at the time of administration of the sulfanilamide. The effect on his general well being was remark-

#### *Course of Administration of Sulfanilamide*

Date	Dose in Grains Three Times a Day
12/ 6/37 to 12/14/37	20
12/11/37 to 12/16/37	10
12/16/37 to 12/18/37	5
12/21/37 to 12/28/37	20
1/ 3/38 to 1/ 4/38	10
1/ 4/38 to 1/ 6/38	15
1/17/38 to 1/19/38	20
1/26/38 to 2/ 2/38	20

able in that his appetite improved, he gained weight and on December 24 was up and around the ward. Jan 1, 1938, he was discharged. His wound was five-sixths healed, there was little discharge and no pain. By March the wound was healed completely. The patient was demonstrated at the meeting of the Society of Clinical Surgery held at the Presbyterian Hospital in May 1938, at which time the treatment of venereal lymphogranuloma with sulfanilamide was advocated.

In July we received the announcement of the patient's wedding.

In addition to these two patients we have had several others suffering with venereal lymphogranuloma who have responded dramatically to the use of sulfanilamide, but for the purpose of this communication the careful observation and study of these two patients and the result of their treatment is sufficient evidence to make the point that sulfanilamide should be given a thorough trial in this type of infection. Why it should help we do not know, since venereal lymphogranuloma is probably a virus disease and as far as we know is the first disease of this type to be beneficially affected by the drug.

Since the writing of this report an article on the same subject by Dr George Shroppshear<sup>2</sup> of Chicago has appeared in the *Illinois Medical Journal* in which are given his experiences with the use of sulfanilamide in venereal lymphogranuloma affecting the rectum. He reports general improvement of the patients and of the inflammatory process in and about the rectum.

## THE TREATMENT OF PNEUMOCOCCIC PNEUMONIA WITH SULFAPYRIDINE

### A PROGRESS REPORT ON OBSERVATIONS IN 100 CASES

HARRISON F FLIPPIN, MD

JOHN S LOCKWOOD, MD

D SERGEANT PEPPER, MD

AND

LEON SCHWARTZ, MD

PHILADELPHIA

The encouraging results of sulfanilamide therapy in infections due to the hemolytic streptococcus, gonococcus, meningococcus and *B coli* have permitted an expectation that eventually there would become available a similar compound which would be effective in the treatment of pneumococcic diseases. This hope has been fortified because of the effects which sulfanilamide itself has been shown to have against the pneumococcus in studies both in vitro and in vivo. Domagk,<sup>1</sup> in his original publication of experimental observations with prontosil, had indicated a belief that this dye was moderately effective against pneumococci, especially of type III. The studies of Nitti, Bovet and Depierre<sup>2</sup> in vitro and of Buttle<sup>3</sup> in mouse peritonitis had suggested that sulfanilamide would act on the pneumococcus, but in a degree which was considerably below its effect on hemolytic streptococci. Moreover, Heintzelman, Hadley and Mellon<sup>4</sup> of Pittsburgh reported some success with the use of sulfanilamide in pneumococcic pneumonia of type III and Finland, Brown and Rauh<sup>5</sup> attributed to sulfanilamide a favorable effect on pneumococcic meningitis when the drug was used in conjunction with other forms of therapy. However, there has been little reason to believe that the specific effects of sulfanilamide on the pneumococcus were of a sufficiently high order to cause, through its general use in all types of pneumonia, any very significant reduction in the mortality or morbidity of this disease.

There are a number of sound theoretical reasons for predicting therapeutic success in pneumococcic pneumonia for any compound which, while pharmacologically similar to sulfanilamide with respect to absorption, toxicity and diffusibility, would at the same time show a higher experimentally demonstrable effectiveness against the pneumococcus. Among these are

1 The bacteriologic similarity of the pneumococcus and the hemolytic streptococcus, so close that Topley and Wilson<sup>6</sup> in their authoritative textbook include them within the same taxonomic group.

2 The absence of extensive tissue breakdown in the area of inflammation in pneumococcic pneumonia, rendering the tissue environment for drug action similar

Dr I S Ravdin showed constant interest and gave helpful suggestions in the conduct of this study.

From the Medical Clinics of the Hospital of the University of Pennsylvania and the Philadelphia General Hospital and the Laboratory of Surgical Bacteriology of the Harrison Department of Surgical Research of the Schools of Medicine, University of Pennsylvania.

in this respect to that obtaining in the types of hemolytic streptococcal diseases which are most susceptible to sulfanilamide.<sup>7</sup>

3 A similar immunologic process of host resistance in the two types of diseases. This is illustrated by the increased bactericidal power of the blood against the infecting organism which has been shown to occur in the majority of cases coincident with recovery from streptococcal puerperal sepsis<sup>8</sup> and from pneumonia.<sup>9</sup>

\* Three fatal cases treated for less than twelve hours are not included

A drug which could be shown to elevate rapidly the bactericidal power of blood and the bacteriostatic power of serum against the pneumococcus, which would be similar to the rise in streptococcal power induced by sulfanilamide<sup>10</sup> might reasonably be expected to bring about a therapeutic response in pneumococcal infection quite analogous to that which attends the use of sulfanilamide in acute hemolytic streptococcal diseases.

Sulfapyridine [2-(*p*-aminobenzenesulfonamido) pyridine] is a compound first prepared by Ewins and Phillips<sup>11</sup> in the course of a search for a substance having a greater experimental effectiveness against the pneumococcus than sulfanilamide and with a sufficiently low toxicity to justify its use in pneumococcal pneumonia. The experimental and clinical use of this compound has already been the subject of a number of highly encouraging reports in the English medical literature. Lionel Whitby<sup>12</sup> has recently presented an admirable review of these studies in his Bradshaw lecture delivered before the Royal College of Physicians of London, and we will offer in the present paper only a brief summary of some of the more significant data which have been published thus far.

Whitby<sup>12</sup> reported that sulfapyridine was chemotherapeutically active in experimental infections in mice against pneumococci of types I, II, III, V, VII and VIII and that sulfapyridine was as effective against hemolytic streptococci and meningococci as sulfanilamide. He further noted a low toxicity of the drug for animals.

Fleming<sup>13</sup> published evidence that sulfapyridine added in vitro (in concentrations which could be obtained therapeutically) would greatly increase the killing power of normal human blood against pneumococci and streptococci. These observations have been confirmed by one of us (J. S. L.) and will be reported on in a later publication.

According to Whitby,<sup>12</sup> the absorption of the drug from the gastrointestinal tract is somewhat more rapid than is that of sulfanilamide, but it is excreted more slowly and in about equal proportions of the free drug and the conjugated acetylated form. Stokinger<sup>14</sup> has found great variation in the proportion of the drug acetylated in different individuals, ranging from 90 per cent to 25 per cent.

Most of the published clinical reports have consisted of presentations of one or two cases in which recovery has taken place under treatment with the drug in the face of types of pneumonia having a generally poor prognosis. However, Evans and Gaisford<sup>15</sup> were able to treat approximately alternate cases in a group of 200 patients with pneumonia admitted to the Dudley Road Hospital, Birmingham. The mortality in the 100 control cases was 27 per cent, which suggests that the type of disease encountered was of at least average virulence. In the 100 treated patients the mortality was 8 per cent, and six of these patients failed to receive an amount of the drug which they considered to be adequate. Some criticism of this report has been made on the ground that typing of the pneumococci was not carried out, and therefore it is possible that the control group was heavily weighted with the more serious types of the disease.<sup>16</sup> However, a fair statistical consideration of the alternate case method of distribution which they used would seem to allow full justification for a belief that the drug might be useful in treating pneumococcal pneumonia.

The possible toxicity of the drug for human beings has received some attention from Marshall.<sup>17</sup> His animal experiments have shown that there is some difficulty in controlling the circulating blood level of the drug and that raising the dose does not result in quantitative increase in blood concentration, which is probably due to erratic absorption of this rather insoluble drug. Sulfapyridine is only sparingly soluble in water (0.1 per cent) and its relatively low toxicity might therefore be explained on the basis of a limited and slow absorption. However, its presence in the blood may be detected as soon as thirty minutes after ingestion.<sup>12</sup> Marshall<sup>17</sup> reported that administration of

TABLE 2—Age Distribution

the soluble sodium salt of sulfapyridine to animals resulted in the rapid development of high and acutely toxic blood concentrations. It was not shown that the administration by mouth of sulfapyridine itself (the preparation now being used for clinical studies) would produce toxic levels of drug absorption in animals. Rather did it appear that limited absorption of sulfapyridine might result in failure in some individual instances to build up a therapeutically effective blood

level Evans and Gaisford<sup>15</sup> did not study blood sulfapyridine concentrations in their patients. The toxic effects which they noticed were generally mild and consisted of cyanosis associated with methemoglobinemia, nausea and vomiting.

Encouraged by the report of Evans and Gaisford,<sup>16</sup> and impressed by the experimental and theoretical considerations favoring a trial of this drug, we commenced in the summer of 1938 a systematic study of the therapeutic possibilities of sulfapyridine in the treatment of pneumonia. Clinical material for this study was obtained

TABLE 3—Race and Sex Distribution

White		Negro	
Males	Females	Males	Females

from the Philadelphia General Hospital, the Hospital of the University of Pennsylvania, the Graduate Hospital of the University of Pennsylvania and several other Philadelphia hospitals.<sup>18</sup> A preliminary report of this study has already been published by two of us.<sup>19</sup>

## ORGANIZATION OF THE STUDY

The first consideration in reaching a proper evaluation of this new chemotherapeutic agent was to obtain a large volume of clinical material which could be uniformly controlled. It was obvious that no one hospital would afford the number of cases which was required for a comprehensive study. Therefore, arrangements were made with individual clinicians and chiefs of service in the several hospitals previously mentioned to permit us to administer the drug to such patients coming under their charge as could be shown to qualify under the criteria of selection which we laid down at the beginning of this study and which will be described in a later paragraph. We considered an attempt to employ the alternate case method of selection, but in view of the basis on which our study was conducted this method seemed to be neither practical nor justifiable.

In all the cases which we accepted for treatment we were able to satisfy ourselves as to the accuracy of the diagnosis, and owing to the fine cooperation which we received we were able to direct the entire course of treatment and to obtain such laboratory data as were required.

We accepted for treatment only such cases as conformed to the following conditions:

1. That a diagnosis of pneumonia could be definitely established by the clinical history and physical examination. An attempt was made to type sputum from each patient, and only the cases in which pneumococci could be typed from sputum or blood culture are included in the present report. In 64 per cent of the cases the diagnosis was confirmed by x-ray examination. In the remaining cases the severity of the illness and the lack of portable x-ray apparatus prevented roentgenologic study. Blood cultures were taken in all but four of the cases, but some of these were not obtained until a few hours after treatment had been started.

2. That the patient should be sufficiently accessible so that he could be followed personally with daily visits

from one or more members of the group. In only three instances did we take the responsibility for permitting other physicians to manage the course of therapy, and in these cases there were extenuating circumstances.

Several patients who had received large doses of serum without apparent effect were given sulfapyridine and recovered, but these cases are not included in the group now being reported. We instituted treatment in every case of pneumonia yielding typable pneumococci in which we were consulted, regardless of complications or the apparent terminal condition. In the compilation of our results, however, we excluded patients who did not live at least twelve hours after the beginning of treatment.

Determinations of the amount of free sulfapyridine in the blood of patients under treatment were carried out in the great majority of cases.<sup>20</sup> These determinations were made by Marshall's<sup>21</sup> method for sulfanilamide, a solution of sulfapyridine being used as a standard.

## DOSAGE

In the majority of cases an initial dose of 2 Gm was followed by 1 Gm every four hours until a total of 25 Gm had been administered. This is the dose schedule recommended by Evans and Gaisford.<sup>15</sup> We attempted to adhere rather closely to this dose schedule in our cases and exceptions were made only in those cases in which severe toxic reactions occurred. On the basis of our experience thus far, however, we are inclined to modify this dosage in cases in which therapy is commenced after the fifth day of the disease. Less drug seems to be required in such cases in order to achieve and maintain recovery, and with suitable exercise of clinical judgment we believe that the treatment may be stopped after a total of only 15 Gm has been given. We plan for the time being to continue the original dose schedule in cases in which treatment is begun before the fifth day of the disease.

## THERAPEUTIC RESULTS

The results of sulfapyridine treatment in the 100 cases of typed pneumococcal pneumonia are indicated in table 1. We have excluded from this report the patients who received the drug for less than twelve

hours. Among these were three fatalities in terminal cases, two of these patients lived long enough to receive only 3 Gm of sulfapyridine in two doses, and one 4 Gm in three doses.

Blood cultures were positive in eight of the cases. Two of these occurred in each of types I and II, and one each in types III, IV, XV and XXIX. Of the eight patients with bacteremia only the one with type IV infection died.

## ANALYSIS OF DEATHS

It is appropriate to call special attention to the fact that three of the four deaths occurred in the type III cases, a mortality rate for this group of 21.4 per cent. This would suggest that in type III pneumonia the combination of sulfapyridine with specific antibacterial antiserum might prove to be the therapeutic method of choice. A decision on this point must be reached with caution however because it is conceivable that in man the effects of rabbit or horse serum and sulfapyridine might oppose each other. It would be unwise without further study to take it for granted that specific serum plus sulfapyridine would be better than the drug alone.

We present, herewith, brief abstracts of the four fatal cases, with postmortem observations in three of them.

**CASE 1**—W. J., a Negro aged 62 years, admitted to the Philadelphia General Hospital Sept. 21, 1938, had been ill for six days prior to admission. On examination he was acutely ill and had signs of pulmonary consolidation involving both lower lobes. On admission the temperature was 102, the pulse rate 140 and the respiratory rate 48. Laboratory studies showed a leukocytosis of 19,000 with 91 per cent polymorphonuclears and 9 per cent lymphocytes. Hemoglobin was 59 per cent

Time of temperature drop in relation to day of disease on which sulfapyridine treatment commenced

(Sahli) and red blood cells 3,480,000. The blood culture was positive for type IV pneumococcus. The patient received a total of 11 Gm of sulfapyridine without improvement and died on September 23. Postmortem examination revealed confluent lobular pneumonia of both lower lobes, acute myocardial degeneration, toxic splenitis, and cloudy swelling of the liver and kidneys. The gastrointestinal tract was essentially normal.

**CASE 2**—E. G., a Negro woman aged 47, admitted Oct. 30, 1938, to the Philadelphia General Hospital, was unconscious at the time of her admission and no history was obtainable. Physical examination, aside from the loss of consciousness, was essentially negative, except for consolidation in both lower lung fields. The temperature was 101, the pulse rate 122 and the respiratory rate 42. The leukocyte count was 32,000, with 94 per cent polymorphonuclears and 6 per cent lymphocytes. Hemoglobin was 52 per cent (Sahli). The red blood cell count was 3,100,000. The sputum showed a predominance of type III pneumococci and the blood urea nitrogen was 70 mg per hundred cubic centimeters. Sulfapyridine was given for a total of 19 Gm with no improvement in the patient's condition. Postmortem examination showed bilateral lobular pneumonia and acute pulmonary edema. There was an acute pericarditis, acute mitral and aortic bacterial endocarditis and marked myocardial degeneration. The kidneys showed severe toxic nephrosis and there was cloudy swelling of the liver. The gastrointestinal tract was essentially normal except for some mucosal atrophy of the stomach.

**CASE 3**—J. S., a white man aged 68, admitted Dec. 5, 1938, to the Graduate Hospital of the University of Pennsylvania, on about the sixth day of his illness, was extremely ill and emaciated and there were signs of consolidation of the left lower lobe, observations which were confirmed by x-ray study. The temperature on admission was 103, the pulse rate 118 and the

respiratory rate 40. Leukocytes numbered 11,800 with 94 per cent polymorphonuclears and 6 per cent lymphocytes. Hemoglobin was 69 per cent (Sahli) and the red blood cell count 3,900,000. The sputum contained many type III pneumococci. Sulfapyridine therapy was instituted and the patient showed some improvement within forty-eight hours but developed signs of acute cardiac failure and died after 21 Gm of the drug had been given. Autopsy was not permitted.

**CASE 4**—D. C., a white man aged 57, admitted to the Graduate Hospital of the University of Pennsylvania Dec. 24, 1938, with somewhat indefinite history as to the onset of acute symptoms, had suffered an upper respiratory infection about two weeks prior to his admission, which was followed closely by chest pain and a productive cough. Some ten years previously he had undergone a left nephrectomy, presumably for calculi. The patient was acutely ill and unconscious. A definite pericardial friction rub and signs of consolidation of the right middle lobe were confirmed by x-ray study. The temperature was 103 F, the pulse rate 128 and the respiratory rate 40. Laboratory studies showed 27,000 leukocytes, 85 per cent polymorphonuclears and 15 per cent lymphocytes. Hemoglobin was 54 per cent (Sahli). Red blood cells numbered 3,400,000, blood urea nitrogen 48 mg per hundred cubic centimeters and blood chlorides 49 milliequivalents. The urine showed abundant albumin, many red blood cells and many granular casts. The sputum was loaded with type III pneumococci. The patient was placed on sulfapyridine two days after admission but succumbed after 25 Gm of the drug had been given. The picture was that of a progressive renal failure, the blood urea nitrogen reaching 105 mg per hundred cubic centimeters. Postmortem study revealed an acute pericarditis and marked myocardial fibrosis. The lungs showed gray hepatization of the right middle lobe, bilateral adhesions and acute pulmonary edema. The right kidney presented many pus pockets with no normal tissue remaining, marked cloudy swelling, and subacute glomerulonephritis. The gastrointestinal tract was essentially normal.

## INFLUENCE OF THE DRUG ON THE COURSE OF THE DISEASE

In evaluating any therapeutic agent, one must consider the effect of the agent on the course of the disease as well as its influence on the final mortality. From the very beginning of this study we have been impressed as were Evans and Gaisford,<sup>10</sup> by the striking frequency with which the initiation of drug treatment was followed within twenty-four hours or less by a critical drop in the patient's temperature. This temperature drop was not immediately accompanied by any significant change in the lung signs but always reflected a marked improvement in the toxemia and the general well-being of the patient. Resolution of the pneumonia then followed within a variable period of days. We are unable to say at this time whether resolution is hastened or retarded by the fall in temperature. There is no reason to believe that the temperature drop is a consequence of any ordinary "antipyretic" process as exercised through the heat regulatory centers. The clinical improvement which accompanied the cessation of fever points rather to the probability that it is a consequence of rapid termination of the invasive or toxemic promoting elements in the infection. The relationship between the temperature drop and the day of disease on which therapy was started is indicated in the accompanying chart.

In several instances there was a recurrence of low grade fever persisting for several days after the initial critical drop. It cannot yet be stated whether continuation of drug therapy beyond the usual four day period is called for in such cases. In our experience, however, clinical recovery did take place without resumption of drug administration, the temperature tending gradually to become stabilized at the normal level as resolution progressed.

In pneumonias from which pneumococci may be typed, the drug has seemed to be quite uniformly effective, though perhaps less effective in type III than in all other types encountered

#### COMPLICATIONS

1 *Empyema*—We have been especially interested in attempting to determine the possible influence of sulfapyridine on the incidence of empyema. This complication was not encountered in any of the cases included in this report, but in a case of type I pneumonia now under treatment an empyema has developed necessitating open drainage

2 *Other Complications*—There were three cases of phlebitis, with recovery in all. The most severe of these was in a patient with a type XXIX infection with bacteremia and bilateral lower lobe consolidation, who was desperately ill on admission. The phlebitis was recognized four days after cessation of treatment, when an unexpected rise in temperature occurred. The patient was able to leave the hospital ten days later without the necessity for a secondary course of treatment

No other complications attributable to pneumococcal infection were encountered. Such complications as might have been due to the drug itself are described in the section on toxicity

#### PHARMACOLOGIC OBSERVATIONS

1 *Toxicity*—The toxic reactions which we observed are indicated in table 4. The untoward effect most frequently encountered was gastric irritability. Nausea was very frequent and was most intense and most likely to produce vomiting during the first twenty-four hours of therapy. In ten cases the vomiting was so severe that it was necessary to stop treatment altogether, but in no case was this done until 12 Gm had been administered. None of these patients died. In thirty cases the vomiting was a source of distress to the patient but was not sufficiently severe to require total cessation of therapy. We experimented with several different methods of controlling the nausea and vomiting

The administration of small amounts of sodium bicarbonate an hour after ingestion of the tablets

Mixing of ground up sulfapyridine tablets with water, fruit juices or milk. The administration of a glass of cold water containing the white of an egg and the juice of a lemon one-half hour before giving the drug. In individual cases each of these adjuvants appeared to improve the tolerance for the drug

The passage of a Jutte tube into the duodenum, permitting the introduction of the drug into the small intestine. This was done both with persistent vomiting and with extremely sick patients who could not take the drug by mouth

Omission of the drug for one or two doses, followed by its resumption. The temporary relief of gastric irritability so achieved often resulted in cessation of vomiting

The introduction of sodium chloride and dextrose intravenously, which is advisable in all patients who show nausea or vomiting. This appears to be a valuable method of minimizing these symptoms as well as of restoring normal fluid and electrolyte balance in the patient who is vomiting. In three instances of severe vomiting we encountered marked depletion of serum chlorides. One patient, a woman of 75 with type IV pneumonia involving the right upper lobe had a drop in temperature in twenty-four hours from 102.3 to 98.7. However, she vomited so much that the drug had to be stopped after only 12 Gm had been given. She became comatose and developed anuria which lasted for fifty-eight hours and the blood urea nitrogen rose to 48 mg per hundred cubic centimeters. Eight hours following the administration of 3 per cent salt solution intravenously she started to void and twenty-four hours later she was completely recovered from the pneumonia

The extreme insolubility of the drug has made impractical its administration through the rectum. We expect in the near future to be able to estimate the value of administering the drug by mouth in an enteric coating

As will be seen in table 4, the other toxic reactions which we have encountered are similar to those associated with sulfanilamide treatment, and are probably manifestations of idiosyncrasy. It has seemed to us that these reactions are not likely to occur as frequently with sulfapyridine as with sulfanilamide. The patients received frequent blood counts and routine urinalysis during the course of treatment. In the majority of cases the white blood cell count tended to drop during the first forty-eight hours coincident with the usual drop in temperature but no cases of agranulocytosis were encountered. In one instance a leukopenia of 1,800 was observed with a normal differential. The red count and hemoglobin likewise fell in a number of cases, but in view of the marked dehydration of most of our patients on admission it has been difficult to evaluate this apparent secondary anemia. As is noted in table 4, we had only one case of acute hemolytic anemia, but in several instances there occurred a drop in the red cell count of over two million, with reduction in hemoglobin of as much as 40 per cent. The urine studies failed to show any signs which would be inconsistent with patients suffering with any febrile illness

2 *Blood Levels*—No data have yet been made available to indicate what constitutes an effective blood level of sulfapyridine in pneumococcal pneumonia. In this study our schedule of dosage was therefore selected empirically on the basis of the work of Evans and Gaisford<sup>16</sup> and this schedule was applied in almost all the cases, regardless of body weight. We made estimates of blood sulfapyridine concentration in most of the cases not for the purpose of influencing dosage but rather to obtain information on (a) the variability of drug absorption in different subjects receiving a uniform dose and (b) the correlation or lack of correlation between the blood sulfapyridine level and therapeutic effect. There was great variability in the concentration of free sulfapyridine among individuals receiving the same dose schedule. The lowest estimate was 1 mg per hundred cubic centimeters and the highest was 18 mg. As suggested by Stokinger,<sup>14</sup> this variability may derive from wide differences in drug conjugation between different subjects. We did not perform determinations of total sulfapyridine (free and conjugated) in these cases. Many patients with blood levels which apparently remained below 3 mg per hundred cubic centimeters enjoyed satisfactory recoveries from pneumonia. The blood levels in three of the patients who died were 12, 15 and 5 mg respectively per hundred cubic centimeters

#### IS THERE CORRELATION BETWEEN BLOOD LEVEL AND RAPIDITY OF RECOVERY?

We have analyzed our data in an attempt to determine whether any correlation would appear to exist between the rapidity of recovery and the concentration of free sulfapyridine in the blood. It would be an important practical consideration in therapy if the failure to establish an "adequate" blood level in a given patient could be shown to militate against achieving a good result. The eleven patients showing blood concentrations of sulfapyridine from 1 to 28 mg were

compared to the eleven patients with blood levels of from 10 to 18 mg per hundred cubic centimeters, affording the "lowest" and "highest" groups. Nine of the eleven patients in the low group showed a drop in temperature within twenty-four hours, while only six of the eleven patients in the "high" group showed this prompt response to treatment. The average duration of disease from the onset of symptoms to the time of temperature drop was 6.25 days for all the patients in whom blood levels were recorded. The same figure for the "low" group was 6.7 days and for the "high" group 6.0 days. It would seem improbable, therefore, that the development of a blood concentration of free sulfapyridine of 10 mg per hundred cubic centimeters or above causes any more rapid primary chemotherapeutic effect than that which occurs with a blood concentration of from 1 to 2.8 mg. We do not believe that these data are sufficiently complete yet, however, to warrant reducing dosage in individuals who show a higher degree of distribution of free sulfapyridine, or increasing dosage in patients who show less complete drug absorption.

## COMMENT

It is a matter of some interest that the reduction in mortality of pneumonia reported by Evans and Gaisford,<sup>16</sup> and by ourselves in this report, corresponds rather closely with the reduction in mortality of hemolytic streptococcal puerperal sepsis reported by Colebrook<sup>22</sup> with prontosil, which was the first sound clinical evaluation of a sulfanilamide derivative in streptococcal disease. Colebrook then recognized the possibility that his results might have been influenced by a possible reduction in the severity of streptococcal infection during the season covered by his study. Similarly we must admit that a possibility exists that the pneumonias we have treated in the fall and early winter of 1938-1939 might not be typical of the disease in its severest form. However, subsequent experience all over the world has tended to confirm the original impression of Colebrook as to the value of sulfanilamide in hemolytic streptococcal infections. Similarly we fully believe that the results of sulfapyridine therapy in pneumonia so far reported are probably representative of its true value in this disease.

## SUMMARY

1 Sulfapyridine therapy for more than twelve hours has been carried out in 100 cases of typed pneumococcal pneumonia in several Philadelphia hospitals.

2 There were four deaths in the series, three of which were in type III infections.

3 There were eight cases of bacteremia with one death.

4 A conspicuous effect of the drug seemed to be its ability to bring about, within twenty-four to forty-eight hours, a critical drop in temperature followed by prompt clinical improvement.

## CONCLUSIONS

Sulfapyridine is an effective drug in the treatment of pneumonia caused by pneumococci which are susceptible of being typed. If sulfapyridine is used with regard for its toxic possibilities, and if the patients in whom it is used are thoroughly studied and carefully followed, it is a therapeutic agent with a satisfactory margin of safety.

## CHRONIC LEAD POISONING

HORATIO B. WILLIAMS, MD

NEW YORK

This paper, written at the request of a number of my professional friends, will place on record the facts regarding several cases of chronic lead poisoning which occurred in my own family. The reason for adding another case record to the already large literature of lead poisoning is twofold. In the first place it seems still to be the general impression of the majority of the medical profession that chronic lead poisoning is characterized always by the classic features of constipation, colic, motor paralysis, blood changes and lead line on the gums. There is, however, a type much more chronic, resulting from a very small intake of lead over a long period of time and eventually showing effects mainly on the nervous system which may mimic almost any of the well known disturbances of that system and may or may not be accompanied by blood changes or other of the signs usually associated with chronic lead poisoning. While there is no sharp line of demarcation between the two types, it would seem to me desirable to speak of the classic type presenting colic, constipation and motor paralysis and coming on after a few weeks' or at most a few months' exposure as subacute lead poisoning.

The second and more important reason for placing the facts of these cases on record is that it was forunately possible to make a thorough study of the situation with careful chemical analyses. Though the results are based on only three people information on the amount of lead competent to produce nervous lesions when taken over a period of several years is so meager that it is believed the information gained from this study may prove helpful.

## LEAD POISONING

In 1931 I came into possession of a very old colonial house at Greenwich, Conn. In modernizing the plumbing system a copper hot water tank was installed for storage of domestic hot water. This was supplied for a year from a shallow well. The following year a deep well was drilled and a large iron storage tank for cold water installed into which water is pumped against air pressure. In the autumn of 1933 I noticed difficulty in maintaining balance while walking on a rough road in the dark. The difficulty seemed less a simple incoordination than a positive disturbance initiated by pressure of the feet against the roughnesses of the road. With rest and attention to general hygiene the condition improved and nothing more was thought of it. The following year, while the family was away on vacation, two Airedale dogs were boarded at a kennel. On our return we were informed that the older dog had been observed suddenly to act queerly and pay no attention to attendants or to offered food. He was isolated and on the following morning he was found totally oblivious to his surroundings, pawing continuously on the concrete floor of his pen. He had pawed the surfaces from the front paws, and arterial blood was spurting from small vessels. A veterinarian was called and gave the opinion that the dog was rabid and advised shooting him without approaching him. This was done and the dog was buried without examination. Other dogs are buried in the same place and it is now unfortunately impossible to identify his bones for examination.

During the following winter I had unusually numerous and trying duties and in the spring found great

<sup>22</sup> Colebrook, Leonard and Kenney. Meave. *Lancet* 1: 1279 (June 6) 2: 1319 (Dec. 5) 1936.

difficulty in reading the examination papers of students. The difficulty was to remember what was contained in any given paper and avoid charging mistakes encountered in earlier papers or crediting previous good performance to the particular one in hand. This really constituted a defect of memory for recent events of a grade so marked that it now seems strange that its significance passed unnoticed. That fact is itself significant of the beginning of a considerable impairment of cerebral function. With the melting of the snow came the realization that walking on a rough road in the dark produced disturbance of the kind noted earlier, but of higher degree. It was also remembered that there had been collisions with furniture in the house when making a sudden turn without taking definite thought and also that on numerous occasions ecchymoses had been observed for which no cause could be assigned. These came to be connected with the accidental collisions mentioned. It now became evident that there was some serious impairment of the nervous system and on the basis of such information as was available without a neurologic examination I proceeded to eliminate one after another the possibilities until I arrived at multiple sclerosis, which, I was not happy to realize, seemed to fit the picture fairly well. It seemed proper to enter a hospital for observation and on explaining the situation, without emphasis on its ultimate significance, to my wife, I elicited the following information. She had observed the incoordination and general clumsiness and had not failed to note the impairment of memory. She had further noticed that the family cat had developed an incoordination of the same type. In fact this cat had fallen a considerable distance the day before from a pergola when he had tried to jump a short distance to a window sill, a thing he had long been in the habit of doing with ease. She further remarked that for some time her fingers had been numb and that she could hardly hold a needle to sew. She had regarded this as one of the unavoidable consequences of the march of time until the housekeeper began to complain of numbness of the legs and she had gradually begun to connect this with my behavior and with that of the cat. This information at once suggested a toxic agent to which we might all have been exposed.

A few months previously Dr. Cassius Watson of the American Telephone Company had called on me and told of a case at first believed to be transverse myelitis, which had occurred in an employee at the Lawrenceville transatlantic sending station. It had been feared that the condition might have been due to exposure to powerful radiation, but at the New York Neurological Institute it had been found that his secretions contained an abnormal amount of lead and under appropriate treatment he recovered. I expressed great surprise that such an effect should occur without the usual classic signs of lead poisoning and learned with interest that a considerable number of such cases were on record.

The remembrance of this conversation suggested an examination for lead and on the following day a twenty-four hour specimen of urine was taken to my colleague Prof. Frederick B. Flinn with a request for a lead determination. It was found that the twenty-four hour elimination of lead in the urine was 0.21 mg. Kehoe<sup>1</sup> gives the normal excretion by this channel as from 0.02

to 0.08 mg. Twenty-four hour specimens showed an elimination of 0.18 mg. by the housekeeper and 0.16 by my wife. When the deep well was drilled, shining particles were observed in the drillings which were thought to be mica. They were. The recollection now suggested the possibility of lead bearing pyrites and a specimen of water from the well was taken. The possibility that the plumber had used lead paint in making up pipe joints suggested the propriety of taking a sample from the storage tank and then for completeness a specimen from the copper hot water tank was taken. No lead was found except in the hot water specimen, which contained 0.18 mg. per liter. Several successive analyses were made, each time with the same result. It was at once suspected that this came from lead paint used on pipe joints and it seemed desirable to determine if possible what the lead content of the water might have been in 1931. This might be done by determining the rate of decrease in concentration.

It may be explained here that this hot water had been used for boiling vegetables, as that saved time and no reason was known for not doing so. Vegetables boiled in water containing small amounts of lead in solution will extract the lead almost quantitatively. The cat was fed some of the cooked vegetables. The dog which died had eaten dog food cooked with this hot water every day for two years except for the time he was at the kennel. His behavior is strongly suggestive of lead encephalopathy. This dog had been vaccinated against rabies within a year.

Having ascertained these facts, I was eager to establish the case as completely as possible before approaching my neurologic colleagues. I carried out a procedure which was recognized treatment for lead poisoning some years ago but is now known to be very dangerous, though I was unaware of this. I took five drops of potassium iodide solution three times daily for a week, at the end of which time the twenty-four hour excretion in the urine had increased to 0.50 mg.

I then entered the Neurological Institute and was examined by Drs. Casamajor and Tilney, who found general impairment of superficial sensation all over the body but more in the lower extremities. Vibratory sensation was completely lost in the feet and very much impaired elsewhere. Temperature and pain sensation were also impaired, but there was no motor disturbance. There was a marked Babinski reflex. At the time I failed to recognize the significance of this in connection with the incoordination in walking, which seemed to be a positive disturbance as well as a matter of lack of afferent impulses. I believe that stimulation of the soles of the feet provoking this reflex was the cause of the exaggeration of the difficulty of walking when the road was rough. There was a well defined Romberg sign. A complete neurologic examination revealed nothing except a multiple neuritis affecting mainly the afferent nerves, though the impairment of memory indicates a beginning effect on the central nervous system and the ultimate outcome suggests that there may have been some cord involvement. An examination of the blood had previously shown no changes. This and the presence of abnormal quantities of lead was confirmed by examination at the institute. It was decided to delead by means of a ketogenic diet as nearly lead free as possible and administration of ammonium phosphate in increasing doses. This was carried out and analyses made afterward showed the elimination in the urine of only traces of lead.

1. Kehoe, Robert A., Thammann, Frederick, and Cholak, Jacob. On the Normal Absorption and Excretion of Lead. II. Lead Absorption and Excretion in Modern American Life. *J. Indust. Hyg.* 15: 257 (Sept) 1934.

The disturbance being less urgent in the cases of my wife and the housekeeper, it was decided not to delead but to trust to gradual elimination on a diet reasonably free of lead.

#### POISONING FROM LEAD ARSENATE

Following the deleading I was advised to eat freely of green vegetables in order to replace calcium. Improvement was rapid and steady for a time. I spent five weeks in the Adirondacks, and green vegetables there were raised locally and required no spraying.

In November I was knocked down by a truck at a street crossing in New York and suffered a simple fracture of the fibula, which healed without deformity. The necessity of going on crutches and of bearing weight exclusively on one foot and the injury to the other are responsible for the fact that I failed for a long time to notice a gradually increasing numbness of the hands and feet. However, in the spring of 1936 it became very noticeable and at length the sensation of numbness of the feet was replaced by a feeling of their entire absence. Examination of the urine now showed a large elimination of arsenic on the part of the entire family. Specimens of the same kind of green vegetables which we had been getting in the market were procured and analyzed by Dr. Flinn. Spinach examined contained lead arsenate corresponding to a concentration of 2 mg. of lead per pound of spinach. String beans carried half that amount. A 5 gallon stone crock was obtained and 3 gallons of 1 per cent hydrochloric acid placed in it. All green vegetables were immersed for one minute, timed with a clock and then thoroughly washed. Three weeks later none of the family were excreting arsenic, though all were still eating green vegetables. I have never recovered from the numbness of the extremities which developed at this time, though it became much less. Numbness was the only complaint of the two women but was never noticeable to me until after the deleading and never a great inconvenience until after the spray residue poisoning.

The use of water from the copper tank was discontinued except for cleaning purposes and the tank was left for a year. At the end of that time the concentration of lead in the water was found to be exactly the same as in 1935 and this was checked by four analyses. The tank was then taken down and all pipe fittings were disconnected and cleaned. It was found that the plumber who put in this tank had used lead paint on the pipe joints. A considerable amount of sludge was found in the bottom of the tank and this was found to contain 339 mg. of lead per gram of the dried sludge. The pipe fittings were pickled in acid and the inside of the tank rinsed with acid and then all was thoroughly washed out. The tank was returned to service and after a week an analysis of the water showed lead in higher concentration than ever before. A consultation was now held with the Copper and Brass Research Association. As a result the tank was removed and examined by the Whitehead Metal Products Company and by the American Brass Company. It appears that the maker had used a light gage copper and to prevent failure on the pressure test he had reinforced all the points where the copper had been perforated for pipe connections with a liberal coating of wiping solder. In some places this was a quarter of an inch thick. The water from the well is very soft and in common with most deep well waters contains a large quantity of carbon dioxide. Its  $pH$  as drawn from the well is about 6 and after boiling it is around 8. It is therefore a

highly corrosive water and from the nature of the water system the dissolved gas could not escape when the water was heated in the copper tank, so that the conditions for solution of lead were favorable. Wiping solder is two-thirds lead. It is not expected that a serious lead hazard will be found to exist in copper hot water tanks. Had this tank been used with a less corrosive water supply the amount of dissolved lead would certainly have been less. It is my understanding that the makers of nonferrous tanks have now agreed not to use any lead alloys in their products. The point of reporting these cases is to emphasize the danger of relatively small amounts of lead when taken over a period of years and the fact that serious damage may result without any of the classic clinical manifestations recognized for years as associated with a more acute poisoning.

The real point of the paper is the light it sheds on the amount of lead required to produce nervous lesions.

It has been shown by Kehoe<sup>2</sup> that the normal American adult excretes daily about 0.3 mg. of lead, principally in the feces. This can only mean that the average intake is of this order of magnitude and if it is not exceeded presumably the bulk of the lead is excreted without ever being absorbed. None of my family suffered from any nervous disturbance prior to 1931. From the amount of water used in cooking vegetables it is possible to deduce that not more than 0.2 mg. of lead was added to the diet from this source. The conclusion seems to be that if the average intake of lead by our population was to be doubled there would be grave danger of a serious occurrence of nervous disorders due to this cause. It might be inferred that the family obtained more lead from spray residues than the average. This may be true, but it is to be remembered that such food was being served in unusual amount at the time of the second disturbance. Also it was definitely the added amount from the water that determined the onset.

Lead arsenate spray is being used not only on fruit but on nearly every kind of vegetable. It is far and away the most effective agent and, all things considered, the most economical. Its use is rapidly extending and there is real danger that unless control measures are instituted the average individual lead intake from this source may reach the danger point in a few more years. Farmers are apt to resent investigations of spray residues. They argue that, since they and their families eat the food products they market and are not poisoned, all talk of danger from that source is nonsense and the investigators are meddling busybodies. However, no one knows how many members of farmers' families may be suffering from disabilities regarded as the act of God or the unavoidable result of age which are really due to this cause. Information supplied to me by a large apple grower indicates that many farmers use lead arsenate in an injudicious manner, employing more than necessary and sometimes spraying only a short time before produce is to be taken to market. He assures me that this is not necessary and that his own apples are perfect with but a small residue remaining at the time of harvesting. In some regions, however, it appears to be necessary to spray seven or eight times in order to secure good results. Sometimes lead arsenate powder is dusted on fruit and vegetables from a dredge box and if this is done shortly before harvest the contamination is liable to be heavy. There is on record

<sup>2</sup> Kehoe, Thamann and Cholak. On the Normal Absorption and Excretion of Lead. p. 285.

a case of fatal poisoning from a single portion of berries which had been so dusted a week before. Unfortunately I do not have the references to this case at hand.

Lead arsenate is practically insoluble in water. In order to avoid having it removed mechanically by wind and rain, various substances are now used to cause it to adhere tenaciously. Ordinary washing with water will not free fruit and vegetables from the residue. It can easily be removed by immersion for one minute in 1 or 2 per cent hydrochloric acid and then washing thoroughly in water. This is being done on a large scale with apples, machinery having been specially designed to perform the operation. This procedure is not applicable to all produce prior to marketing as it results in deterioration of some products, for example lettuce.

Information is urgently needed as to the amounts of spray residue on produce offered for sale and also on human tolerance. It is most important that the safest effective method of using lead arsenate should be determined and that farmers should be induced to cooperate with health agencies in working out a procedure which will result in good produce without a serious hazard. Modern rapid transportation facilitates the spread of insect pests, calling for more extensive use of poison. It also facilitates transport of fresh fruits and vegetables so that they are now being consumed the year round. Instead of a seasonal hazard there is now a continuous one. It is important to know just how far we are from a general threat to health and that careful watch be kept for signs that we may be approaching the danger point.

## Clinical Notes, Suggestions and New Instruments

### TESTOSTERONE PROPIONATE IN THE TREATMENT OF FUNCTIONAL UTERINE BLEEDING

H. S. RUBINSTEIN, M.D., BALTIMORE

Because it was observed that repeated injections of testosterone propionate inhibited the growth of the graafian follicle and definitely inhibited ovulation in the albino rat, and because when this hormone was given to the male it failed to lead to hirsutism,<sup>1</sup> it was deemed safe to study its effect in a case of functional uterine bleeding.

A white married woman aged 35 had been obese for five years and had had excessive vaginal bleeding for about ten years. Her family history was irrelevant. She had been stout as a child but had otherwise been healthy. Menstruation began at the age of 13 and had recurred every twenty-eight days for a duration of three days with neither pain nor discomfort until ten years before. At that time the duration began to increase, and after a few months each period lasted nine days, although the twenty-eight day cycle was maintained. For the past seven years the menses had been very irregular, recurring twice monthly on many occasions and lasting from ten to twelve days with staining almost continuous.

The patient married at 18 and lived compatibly with her husband in spite of a sexual frigidity which had existed for the duration of her marriage. There had been four pregnancies. The first occurred fifteen years, the second thirteen years and the third nine years before. These three ended in stillbirths because of a narrow birth canal. Six months before she had

given birth through cesarean section to a girl weighing 5 pounds 4 ounces (2,381 Gm.), who is developing normally.

She spontaneously associated her menstrual irregularity with her obesity, stating that before this irregularity she weighed 129 pounds (58 Kg.). She was 61.8 inches (157 cm.) tall. Her weight gradually increased until she weighed 195 pounds (88 Kg.).

A review of her diet revealed that she ate no more than the average woman. There were no digestive upsets, but constipation was severe. There was excessive thirst, so that she drank about ten or twelve glasses of water daily, but polyuria was moderate. There were no nervous symptoms, and a psychiatric survey failed to disclose any marked emotional or content disorder and revealed no psychogenic basis for her frigidity.

At examination the temperature was 96.2 F., the pulse rate 72, the respiratory rate 18 and the blood pressure 140/70. She was obese, the fat being distributed over the shoulder girdle, upper part of the back, breasts, abdomen, thighs and pelvic girdle. The wrists and ankles were thin.

The distribution of hair was feminine; the hair on the scalp was coarse but not brittle. The eyes, sinuses, nose and mouth showed no pathologic changes. The thyroid gland was small but definitely palpable when the patient swallowed. It contained no nodules or other abnormalities.

The chest was rather emphysematous, with shallow expansion. The breasts were pendulous but contained neither abnormal masses nor regional lymphadenopathy. The heart and lungs were normal. The abdomen possessed a panniculus adiposus and a midline scar (cesarean) just distal to the umbilicus.

Neurologic survey gave normal results. The superficial abdominal reflexes could not be elicited, however. This was obviously due to the obesity.

Laboratory studies of the blood and urine revealed no deviation from the normal. The basal metabolic rate, however, was found to be minus 13 per cent and specific dynamic action<sup>2</sup> was found to be 7 (somewhat depressed). In addition, microscopic examination of a biopsy specimen, performed by Dr. Emil Novak, disclosed a nonsecretory, interval type of endometrium.

Because of these observations the diagnosis was (1) hypopituitarism with functional bleeding, (2) secondary hypothyroidism and (3) chronic constipation.

The patient was placed on a restricted diet (protein 50 Gm., carbohydrate 90 Gm., fat 60 Gm., calories 1,100), and her constipation was combated through establishment of habit, regulation of diet and cascara. Thyroid  $\frac{1}{2}$  gram (0.03 Gm.) three times a day was given because of her low basal metabolic rate, this dose being quickly raised so that at the end of two weeks it was 2 grains (0.13 Gm.) three times a day. Within one month the basal metabolic rate had risen to plus 4 per cent and the weight had been reduced 8 pounds (3.6 Kg.), but the vaginal bleeding persisted.

March 16, 1938, 5 mg. of testosterone propionate (perandren-Ciba) was given subcutaneously. A similar dose was given March 20. On March 22 bleeding stopped. Injections were given twice weekly for the next three weeks but were discontinued during the fourth week. On April 21 the patient began to menstruate, this period lasting five days. There had been no staining from March 22 until the onset of this period. Two days after cessation of the menstrual flow, treatment was resumed, two injections being given for one week after menses and one injection weekly for the next two weeks. Injections were discontinued thereafter so that menstruation could occur unimpeded. On May 19 the patient began to menstruate this period lasting five days.

The same procedure, i.e., two 5 mg. injections for one week and one 5 mg. injection for the next two weeks with a treatment-free interval thereafter, was followed. On June 16 menses occurred normally. There was a moderate flow for two days.

From the Research Laboratory, Surgical Division, Sinai Hospital City Pharmaceutical Products, Inc. partially defrayed the expense involved in this study.

<sup>1</sup> Rubinstein, H. S. The Induction of Sexual Maturity in the Centrally Hypoplastic Adult. *J. A. M. A.* 111: 1818 (Nov. 12) 1918.

<sup>2</sup> Goldzieher, Max A. *Practical Endocrinology*. New York: D. Appleton-Century Company, 1937.

which gradually diminished until June 20, when it stopped completely. The patient is now being maintained on the same regimen.

## COMMENT

It is difficult in the present state of knowledge to explain exactly why the testis hormone has favorably influenced the functional bleeding in this patient. Chemically, testosterone propionate (perandren Ciba) is similar in structure to progesterone<sup>3</sup> and like progesterone<sup>4</sup> has been found to retard follicular maturation and to inhibit ovulation.

## Council on Pharmacy and Chemistry

### PRELIMINARY REPORT OF THE COUNCIL

THE COUNCIL HAS ADOPTED THE DESIGNATION SULFAPYRIDINE AS A NONPROPRIETARY NAME FOR THE DRUG 2 (PARA AMINOBENZENE SULFAMIDE) PYRIDINE OR SULFANILAMIDOPYRIDINE (THE JOURNAL JANUARY 7 P. 49). THE COUNCIL HAS ALSO GIVEN CONSIDERATION TO A REPORT ON THE STATUS OF THIS DRUG PREPARED BY DR. PERRIN H. LONG OF THE JOHNS HOPKINS MEDICAL SCHOOL. THE COUNCIL AGREES WITH DR. LONG'S CONCLUSIONS. IT FEELS THAT IN THE LIGHT OF AVAILABLE EVIDENCE THE GENERAL USE OF THE DRUG DOES NOT SEEM TO BE WARRANTED AT THE PRESENT TIME. THE COUNCIL FEELS THAT BECAUSE OF THE DEFINITELY EXPERIMENTAL STATUS OF THE DRUG IT SHOULD BE USED ONLY BY PROPERLY QUALIFIED PERSONS FOR INVESTIGATIONS OF ITS VALUE IN PNEUMOCOCCIC, SEVERE STAPHYLOCOCCIC AND TRIPYLANDER'S BACILLUS INFECTIONS. THE COUNCIL EXPRESSES ITS APPRECIATION OF DR. LONG'S AID AND AUTHORIZES PUBLICATION OF HIS REPORT AS A PRELIMINARY STATEMENT ON THE STATUS OF SULFAPYRIDINE.

PAUL NICHOLAS FEECH, Secretary

### SULFAPYRIDINE

PERRIN H. LONG, M.D.

BALTIMORE

In the May 28, 1938, *Lancet*, Whitby<sup>1</sup> reported that sulfapyridine (2 [para aminobenzene sulfamide] pyridine, "M & B 693," "Dagenan") was an efficient chemotherapeutic agent in the treatment of experimental hemolytic streptococcal, meningococcal and pneumococcal infections in mice. The therapeutic activity of this compound seemed to be especially noteworthy in experimental infections produced by types I, II, III, V, VII and VIII pneumococci. Subsequently Whitby<sup>2</sup> stated without giving experimental detail that sulfapyridine was also an active chemotherapeutic agent in the treatment of staphylococcal infections in mice. My associates and I<sup>3</sup> have, in the main, confirmed Whitby's experimental observations regarding the therapeutic efficiency of sulfapyridine in experimental hemolytic streptococcal, pneumococcal, meningococcal and staphylococcal infections and in addition have found that this compound is also effective in experimental Friedlander's bacillus and *Clostridium welchii* infections in mice. Our experience would lead us to believe that the drug is about as efficient as is sulfanilamide in the treatment of experimental streptococcal, meningococcal and *Clostridium welchii* infections in mice and somewhat superior to sulfanilamide in the treatment of experimental pneumococcal, Friedlander's bacillus and staphylococcal infections in mice. While the results noted in the treatment of the three latter experimental infections are better than we have

observed with any other chemotherapeutic compound, they do not approach the brilliant results which have been noted when sulfanilamide has been used in the treatment of experimental streptococcal infections in mice.

Whitby<sup>1</sup> stated that sulfapyridine had a low toxicity for animals and Wien<sup>4</sup> has reported that the L.D. 50 of the drug is 166 Gm. per kilogram for mice and 15 Gm. per kilogram for rats. We<sup>5</sup> were unable to obtain an L.D. 50 in mice and concluded that its low acute toxicity for animals resulted from the fact that very little of the drug was absorbed. Wien<sup>4</sup> also stated that large doses of the drug did not bring about changes in the blood or urine of animals. Marshall, Bratton and Litchfield<sup>6</sup> have noted that the administration of increasing doses of sulfapyridine in acacia suspensions to mice "yielded blood values of increasing amount but these values were not at all proportional to the dose." They next prepared the soluble sodium salt of the drug and found that with moderate doses the blood levels attained in mice were roughly proportional to the dose. Even more interesting was their finding that the drug when absorbed (as occurs when its sodium salt is administered) was more toxic than sulfanilamide. This is definite proof of the invalidity of Wien's observations and again shows the futility of accepting data regarding the toxicity of a poorly soluble compound when such results are unaccompanied by observations concerning the absorption of such a compound.

Whitby<sup>2</sup> has reported that "despite its relative insolubility, the drug is rapidly absorbed, even more rapidly than sulfanilamide and it is excreted somewhat more slowly." We are somewhat at variance with Whitby on this point. In our experience<sup>7</sup> sulfapyridine is irregularly absorbed in man and animals and in comparison with sulfanilamide is also more slowly and definitely less well absorbed. We agree with Whitby<sup>2</sup> that the drug is excreted slowly. We have noted that, following the administration of single doses of 0.05 or 0.10 Gm. of sulfapyridine per kilogram of body weight to human beings, from 39 to 79 per cent of the drug was excreted in the urine in from three to four days. We have found that the concentrations of the drug in the blood of both man and animals are better sustained following the administration of single doses of sulfapyridine than is the case when comparable doses of sulfanilamide are given. Our experience leads us to believe that in certain individuals much more sulfapyridine is present in the blood in the conjugated form than one would expect in the instance of sulfanilamide. The drug seems to pass over into the spinal fluid or into exudates in from one half to three fourths of its concentration in the blood.

Whitby<sup>8</sup> has stated that in experimental pneumococcal infections the drug acts by bringing about degenerative changes in the capsular material of the pneumococcus. Telling and Oliver<sup>9</sup> believe they have confirmed this. However, Fleming<sup>10</sup> and we<sup>5</sup> have been unable to see specific changes in the capsules of pneumococci observed in peritoneal exudates obtained

from mice in which sulfapyridine had been used in the treatment of experimental pneumococcal peritonitis. Both Fleming<sup>10</sup> and we<sup>11</sup> have noted that the multiplication of susceptible organisms is hampered both in vivo and in vitro following the administration of sulfapyridine to mice or culture mediums. We have been unable to confirm Whitby's<sup>8</sup> observation that mice infected with pneumococci and treated with sulfapyridine are immune on recovery to subsequent infection with the homologous organism.

Soon after Whitby's original communication, Telling and Oliver<sup>9</sup> reported on the successful use of sulfapyridine in a patient severely ill with type III pneumococcus lobar pneumonia. Then Evans and Gaisford<sup>12</sup> described the effects of the drug in the treatment of 100 cases of pneumococcal lobar pneumonia in which the case fatality rate was 8 per cent as compared with 27 per cent in a control series observed at the same time. While these investigators presented little data regarding the pneumococcal types encountered in their patients, and no information regarding the incidence of bacteremia, their results suggest that sulfapyridine therapy altered the course of the disease and its fatality rates in their patients. Subsequently other observers<sup>13</sup> have reported on the use of the drug in the treatment of pneumonia but, because of the small numbers of patients treated, no significant data have been added by these reports. Our own experience with the use of sulfapyridine in the treatment of lobar pneumonia has been limited, but in certain instances the drug has seemed to have a beneficial effect on the course of this disease. However we feel that, until there is evidence that sulfapyridine is as valuable as specific antipneumococcus horse or rabbit serum in the treatment of lobar pneumonia, the use of potent types I to VIII and type XIV serum should not be abandoned.

Several papers<sup>14</sup> have been published concerning the successful use of sulfapyridine in the treatment of pneumococcal meningitis. Dr Horace Hodes of Sydenham Hospital of Baltimore has treated four such patients with this drug. One patient recovered and, of the three who died, life seemed to be definitely prolonged in two.

The drug has been used with some success in the treatment of staphylococcal infections associated with bacteremia.<sup>15</sup> We have noted that the institution of sulfapyridine therapy was followed by a rapid sterilization of the blood in three of five patients ill with staphylococcal bacteremias.

Dimson<sup>16</sup> reported that treatment with sulfapyridine brought about a prompt recovery in a patient suffering from chronic meningococcemia. Hobson and McQuaide<sup>17</sup> noted recovery in six of six patients ill with meningococcal meningitis and treated with the drug.

Durel<sup>18</sup> in a series of articles has stated that sulfapyridine is at least as effective as sulfanilamide in the treatment of gonorrhea. McElligott<sup>19</sup> and Lloyd,

Erskine and Johnson<sup>20</sup> have reached the same conclusion. Prebble's<sup>21</sup> results, when sulfapyridine was used in the treatment of gonorrhea, do not seem to be as good as one would expect from the use of sulfanilamide, and Cokkinis<sup>22</sup> is definitely of the opinion that the superiority of sulfapyridine over sulfanilamide in the treatment of gonorrhea has yet to be proved. A review of these reports leads us to conclude that, while the drug has certain beneficial effects in the treatment of gonorrhea, claims of its therapeutic superiority are undoubtedly premature.

The toxic manifestations of sulfapyridine therapy in man are essentially those observed when sulfanilamide is used, with the possible exception of acidosis, which as yet has not been described. We have seen nausea, vomiting, dizziness, headache, fever, morbilliform rashes and tingling of the extremities in patients who were under treatment with the drug. Dr Colin McLeod of the Hospital of the Rockefeller Institute has observed two cases of acute hemolytic anemia in which sulfapyridine was being administered at the time the blood dyscrasias developed. Johnston<sup>23</sup> has reported the occurrence of agranulocytosis in a patient receiving sulfapyridine, and we have seen one patient in whom the development of agranulocytosis seemed to be related definitely to sulfapyridine therapy.

#### CONCLUSIONS

1 On the basis of the available experimental and clinical evidence, careful therapeutic trials of the effects of sulfapyridine in pneumococcal, severe staphylococcal and Friedlander's bacillary infections seem warranted.

2 Good evidence is not at hand that the drug is as effective as, or superior to, sulfanilamide in the treatment of hemolytic streptococcal, meningococcal, gonococcal or Welch bacillus infections.

3 The drug is irregularly absorbed and slowly excreted.

4 The toxic manifestations of the drug seem to be no less severe and no less frequent than those witnessed in the course of sulfanilamide therapy.

5 Rational schemes of therapy with this drug have not as yet been presented.

#### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

#### ANTIPNEUMOCOCCIC SERUM, TYPE II (See New and Nonofficial Remedies, 1938, p. 399)

The Gilliland Laboratories, Inc., Marietta, Pa.

*Antipneumococcal Serum Refined and Concentrated Type II*—Prepared by immunizing horses with intravenous injections of the virulent and avirulent cultures of type I and type II pneumococci. Trial bleedings are made at frequent intervals and when the serum has reached a sufficient degree of potency for type II pneumococci the horses are bled aseptically and the serum is refined and concentrated by the method of Lloyd D. Felton (*J. Infect. Dis.* December 1928, p. 543). The concentrated product contains type I pneumococcus antibodies but not in therapeutically important amounts. After concentration sterility tests are carried out in the manner prescribed by the National Institute of Health and safety tests are carried out by injection into white mice and guinea pigs. The potency of the product is expressed in terms of the unit described by Felton (*Boston M. & S. J.* May 15, 1924, p. 819; *J. Infect. Dis.* September 1925, p. 199; October 1925, p. 309), the unit being 1/100 cc. of the control serum (P 11) distributed by the National Institute of Health. Marketed in packages of one syringe containing 10,000 units and in packages of one syringe containing 20,000 units each accompanied by a vial of dilute serum (1:10) for the sensitivity test.

## SULFAPYRIDINE—THE NEW SULF- ANILAMIDE DERIVATIVE

For more than two years the drug sulfanilamide has attracted more interest than any other therapeutic agent, because of the spectacular results which followed its use in many conditions including certain specific effects in infections with the beta strain of the hemolytic streptococcus. The extensive employment of the remedy has indicated not only the truly remarkable results of the drug but also its decided toxicity. Repeatedly *THE JOURNAL* and the Council on Pharmacy and Chemistry have warned against indiscriminate administration.

As always happens after a new discovery in the field of medicine, chemists everywhere, particularly in the employ of pharmaceutical houses, have been stimulated to attempt to find derivatives of sulfanilamide which might be still better than the parent compound. A host of such products has been announced in the chemical and pharmacologic literature. Most have been disappointing in results and frequently more toxic than sulfanilamide. Early in 1938 Whitby<sup>1</sup> reported that the pyridine derivative of sulfanilamide (2-[para-aminobenzenesulfonamido] pyridine) had promise of being efficient in the treatment of experimental hemolytic streptococcus, meningococcus and pneumococcus infections in mice. Moreover, the product apparently has superiority over sulfanilamide in experimental infections with pneumococcus, particularly of types I, II, III, V, VII and VIII. Elsewhere in *THE JOURNAL* is a preliminary report of the Council on Pharmacy and Chemistry on sulfapyridine prepared by Dr. Perrin H. Long.<sup>2</sup> While this report is favorable, it is conservative. The reports of the effects of sulfapyridine in pneumococcal, severe staphylococcal and Friedlander's bacillus infections seem to warrant its use under carefully controlled conditions. The drug is apparently not as effective as sulfanilamide or superior to it in the treatment of hemolytic streptococcus, gonococcus, meningococcus or Welch bacillus infections. Sulfapyridine is irregularly absorbed but slowly excreted, as

shown by the work of Marshall.<sup>3</sup> The toxic manifestations of the drug are as severe and as frequent as those witnessed in the course of sulfanilamide therapy. Indeed it may be expected that in some cases the toxicity will be greater because of the presence of the additional pyridine molecule. Much investigative work remains to be done to work out rational schemes of therapy with this drug. Its use in pneumonia, however, as reported from investigators in the field, is frequently more startling than sometimes follows the use of sulfanilamide in severe hemolytic streptococcus infections.

In this issue of *THE JOURNAL* appear also articles by Barnett, Hartmann, Perley and Rihoff of St. Louis (page 518) and by Flippin, Lockwood, Pepper and Schwartz of Philadelphia (page 529) on the treatment of pneumococcal pneumonia with sulfapyridine. In general their results are in keeping with Dr. Long's observations as outlined in the preliminary report of the Council. The St. Louis investigators tried the drug on twenty-three infants and children, including fourteen who had pneumonia. Their results on these young patients were in general confirmatory of the results which have been obtained from the use of the drug in adults. They report that cyanosis due to the accumulation of methemoglobin was encountered in most of the severe cases. In an addendum to their article the St. Louis group states that fifty-seven additional cases have been treated with sulfapyridine, including twenty-six cases of pneumonia. The results in pneumonia were similar to those already mentioned. Beneficial results were not observed by them in treatment of seventeen miscellaneous cases of staphylococcal infections and dysenteries. The Philadelphia workers report a reduction in mortality in pneumonia following the use of this drug. Of 100 cases of typed pneumococcal pneumonia, they report four deaths in the series, three of which were in type III infections. From eight cases of bacteremia they report one death. However, they, like others, warn concerning its toxic possibilities and caution that the patients on whom it is to be used should be carefully studied.

Others feel less optimistic about the value of the drug based on present evidence. Bullock, Plummer and Finland have sent a communication to *THE JOURNAL* (this issue, page 570) on the present status of sulfapyridine in the therapy of the pneumonias.

During the past year sulfapyridine has been introduced into the therapy of pneumonia in England, and this drug is now having a number of clinical trials in this country. The earliest clinical reports and subsequent ones from England were made without proper controls and the data presented were grossly inadequate for any evaluation. Those who have spent many years in the study of pneumonia will testify to the difficulties in assessing the value of any agent in this disease before a large number of cases have been accumulated, each properly studied with respect to etiology, bacteremia and the clinical factors affecting death rates. The untoward effects and possible dangers of the remedy must also be assessed. It would be unfortunate if the appearance of a new therapy, no matter

<sup>3</sup> Marshall, E. K. Jr. *Science* 88:597 (Dec. 23) 1938.

how promising, were to cause the abandonment of agents whose curative efficacy and life saving qualities have become established. In the case of pneumonia, sulfapyridine must still be considered as an experimental drug and, as such, should be used only under controlled conditions.

While there is no reason to suspect the purity of sulfapyridine, standards have not yet been published for determining the identity and purity of the product, the pharmacologic and clinical data are insufficient.<sup>4</sup>

In the light of evidence now available, the general use of sulfapyridine does not seem to be warranted at present. Because of its definitely experimental status, the drug should be used under conditions of controlled investigation. Under the new law passed by Congress in 1938 a new drug may not be released for interstate sale until it has been licensed. Under the regulations, manufacturers of new products may obtain permission for properly qualified workers to investigate the preparations. The Food and Drug Administration has a great responsibility. It has not released sulfapyridine for general sale in interstate commerce and for this action it deserves commendation. The law gives opportunity for the first time for a drug to be tried *first* in hospitals which have facilities for observing all its manifestations. Such a procedure is established in the interest of the public and is much preferable to the former custom of frequently placing the drug on the market before adequate tests had been made. Most likely sulfapyridine will be released, but it is a wise course to withhold it from general distribution until observations now under way are completed.

#### 'PRESUMPTIVE,' 'EXCLUSION' AND 'SCREEN' TESTS FOR THE SERODIAGNOSIS OF SYPHILIS

An increasing widespread use is apparent of tests for syphilis said to be so sensitive that a negative result "excludes" syphilitic infection<sup>1</sup> while a positive result is "presumptive" evidence of syphilis.<sup>2</sup> Confirmation by a less sensitive and more specific procedure is, of course, necessary before such tests can be considered of diagnostic significance. Several aspects of these tests should give pause to serologists and physicians alike, for they promise to cause serious errors, both of omission and of commission, in the diagnosis and treatment of syphilis.

The first criticism concerns nomenclature. Not merely does no laboratory test yet devised "exclude" syphilis, but no laboratory test even excludes the presence of serum reagin.<sup>3</sup> Moreover, it is not necessarily true that a serum giving a negative Kline exclusion or Kahn presumptive result will be negative by every other

technic used. In any extended series of tests, certain syphilitic serums are detected only by an ordinarily less sensitive procedure. These paradoxical results are particularly common when both a flocculation and a complement fixation test are used. Finally, the flocculation phenomenon is peculiarly susceptible to zone reactions, i. e. false negative results caused by the presence of excessive amounts of reagin. A serum may be negative with any flocculation test, screen tests included, when tested as whole serum, yet the complement fixation test may be clearly positive and the flocculation procedure may be similarly positive if the serum is tested in 1:10 or 1:20 dilutions. For these several reasons it is clear that the term "exclusion" test is misleading. It would seem preferable to call these procedures "screen" tests, for such they are, and thus to avoid the present confusing terminology.

A far more important criticism applies not to the tests but to the manner in which they are used. Certainly it was not the intention of their originators that these tests were to be used as diagnostic measures, yet reports as difficult to evaluate as "exclusion test positive, diagnostic test doubtful," presented without explanation to the physician, invite the possibly mistaken diagnosis of syphilis. In the hands of experts these exclusion procedures may be highly specific. In the average laboratory they are often not specific, and experience has shown a general average of false positive reactions ranging from 1 to 10 per cent. When a laboratory obtains a positive "exclusion" or "presumptive" result, the burden of proof rests on the laboratory that such a result is not due to laboratory error but reflects the actual presence of reagin.

Indeed, one might properly insist that the clinician be not informed of the result of a hypersensitive screen test unless it is negative, for the weeding out of negative serums is its only proper function. No matter what result is obtained when a positive or doubtful screen test is checked by one or more specific diagnostic tests, only the latter should be reported by the laboratory, and the result of the "exclusion" or "presumptive" test should be withheld. The objection may be raised that a report "exclusion test positive, diagnostic test negative" is a valuable guide to treatment in cases of known syphilis and that such a result indicates the persistent presence of traces of reagin. That point of view is debatable. To the extent that the "exclusion" test may be false, it may be as much in error with syphilitic serums as with nonsyphilitic serums. More important, antisyphilitic treatment is not directed against the presence of serum reagin, it is directed against the spirochete. The modern treatment of syphilis properly pays little heed to the serologic response and more to the patient.<sup>4</sup>

Used solely as an intralaboratory procedure to facilitate the recognition of negative serums, the hyper-

<sup>4</sup> The drug is being manufactured in this country by Merck & Co. New York (under license from May and Baker of England) and also by Calco Chemical Company of Bound Brook, N. J. There are patent difficulties yet to be solved by the two firms.

sensitive screen test may fill a useful function, but to report positive or doubtful screen tests to the physician as quasidiagnostic tests which he must weigh and interpret cannot fail but cause confusion and invite the mistaken diagnosis of syphilis

### HEALTH PROGRESS THROUGH EDUCATION

In recent years a steady trend toward a return of preventive medical practice to the family physician and the family dentist has become apparent. Among the leaders in this trend has been the W. K. Kellogg Foundation of Battle Creek, Mich. A summary of the reports of the Michigan Community Health Project<sup>1</sup> involving seven counties in Michigan, namely Allegan, Barry, Branch, Calhoun, Eaton, Hillsdale and Van Buren, has just been issued. This community health project was begun in 1931, when approximately \$12,000 in grants was made to a single community, in 1937-1938 the grants had grown to \$617,211. In cooperation with the county boards, the county medical societies, the dental organizations and citizens' groups, the foundation has assisted in providing community health organization, postgraduate education, camps, library facilities and aid to hospitals, schools, youth organizations, recreation and libraries.

The community health organizations are typical county health units with full time medical directors and the necessary accessory personnel. They are operated in cooperation with the county board of supervisors, the state department of health and the Kellogg Foundation but in close cooperation with medical and dental societies, hospitals, school boards and other professional groups. Educational activities are emphasized. Thus, postgraduate courses have been provided at various universities for seventy-three physicians, forty-five dentists, twenty nurses, 559 teachers, 154 ministers and eighteen veterinarians, as well as for 161 school directors, eighty township supervisors, seventeen editors, twelve social workers and three laboratory technicians. This contribution to training of personnel already at work in the communities in most instances is a fundamental feature of the Kellogg plan which gives it far reaching significance. The education which these men and women have received has qualified them for continuance of work even if the support of the Kellogg Foundation should be withdrawn. The mere underwriting of services put into effect by enticing well trained personnel from other fields does not go to the root of the matter as effectively as does the Kellogg Foundation through its educational approach.

The service activities of the community health departments are designed largely for educational purposes and for arranging help before and after the birth of a baby, for medical, dental and special examinations,

for immunization against communicable disease, for the correction of physical defects and for talks to study groups and meetings.

Other avenues over which existing community resources have been built up are indicated in the following items selected more or less at random from the report. Library technicians are provided in eight hospitals, and two libraries became self supporting during the year, x-ray equipment, oxygen tents, fracture tables, respirators and other special equipment were provided eight hospitals, three hospitals were given grants for buildings, as were nine major school building projects.

The support of the project is summarized in the following statement: "The challenge is to see whether local leadership so stimulated can develop really effective methods to meet community needs and thus advance the cause of child health, education and welfare over many fronts, local, state and national."

### Current Comment

#### THE MULTIPLE ACCIDENT DRIVER

A recent study<sup>2</sup> of the accident repeater is based on the reports of more than 40,000 accident drivers in the Chicago parks over a three year period. Approximately 1,000 of these were repeaters. As far as the figures would allow, it was concluded that the accident repeater is a driver who is more likely to have accidents in the future than the average driver. Furthermore, the repeater's accidents occur closer together and he accumulates more personal injury accidents and is more often "at fault" than the average single accident driver. He is more likely to be a man than a woman, but he has his accidents under about the same light, weather and road conditions as the nonrepeater. The taxi or bus driver repeater varies little from a private car driver on a mileage exposure basis, although at first glance his record seems distinctly worse. Suggestive information on other characteristics was obtained but for various reasons was not available for detailed analysis. It was recommended in part as a result of this report that the accident repeater be considered as one of the most important elements in the accident picture, that state drivers' license laws empower the proper officials to suspend or revoke the licenses of habitual accident repeaters, that civic authorities maintain a properly indexed file of traffic accidents and that drivers of commercial vehicles, especially those carrying paying passengers, be selected with the greatest of care as to their mental and physical capabilities and their records as "safe drivers." It is felt, indeed, that drivers' license laws should require that the examination for drivers of vehicles carrying paying passengers be made more rigid than the general driver's examination because of the fact that the ability of the commercial driver has a direct relation to the safety of his passengers.

# ORGANIZATION SECTION

## AMERICAN MEDICAL ASSOCIATION STUDY OF MEDICAL CARE PROVIDENCE MEDICAL ASSOCIATION'S REPORT

### PROVIDENCE, RHODE ISLAND

The Providence Medical Association is a district society made up of physicians located in the cities and towns listed in table 1, which are included in the survey

Table 2 lists the number of questionnaires distributed and the number returned and used in the study of the need and supply of medical care in this district. The percentage of returns shows that the welfare and relief agencies, the nurses' organizations and the health departments—the three organizations that are in daily contact with the people who are least able to pay for medical services—are well represented in this study. These organizations are in almost complete agreement on the question of the need and supply of medical care. Their answer was that they knew of no instance in which a person in need of medical services of any kind was unable to obtain the necessary service. They also reported that they were able to arrange for needed medical, dental or hospital care for all persons who requested aid in obtaining such care.

The committee appointed by the Providence Medical Association to conduct the survey prepared a very comprehensive and concise report of the data that was recorded on the returned forms. This report summarizes the information included in the complete study so well that it is given below without any further discussion.

The Committee for the American Medical Association Survey of the Need and Supply of Medical Care has carried on the task of canvassing the district included by this association, covering a population area of 353,197 persons. Survey forms were sent out with return enclosures to every physician, dentist, hospital, nursing agency, health department, welfare

TABLE 1—Places Included in the Survey

Name	Population
City of Providence	243,006
City of Cranston	44,533
Town of Barrington	5,501
Town of Bristol	10,885
Town of East Providence	30,113
Town of North Providence	11,770
Town of Warren	7,389
Total	353,197

and relief agency, school department (as well as private school), college and pharmacy.

The returns on these surveys have been practically 100 per cent in the case of the smaller groups, 42 per cent for the doctors and 24 per cent for the dentists. The committee has recognized the difficulty encountered in so many instances in the efforts of the physicians to give exact and complete statistics as required by the survey forms and is appreciative of the conscientious effort made by those who returned the forms to provide the basis for this tabulation of the district.

This report is intended as a brief summary of the findings of the committee to date and will be supplemented by a final report later in the year.

The matter of medical facilities was of first consideration, and the statistics compiled show there is a doctor available to every 774 persons in the district, a dentist to every 1,576, and a nurse to every 500. [The greatest distance the nearest physician would have to travel to reach persons in this district is 5

TABLE 2—Distribution of Forms

Other organizations	0	0	0
Pharmacists *			

\* The survey of the pharmacists was conducted by the Rhode Island Pharmaceutical Association for the whole state. It is impossible to separate the data reported by the pharmacists in this district from the state report.

miles.] Every type of hospital accommodation is available, and the district hospital facilities report a total bed capacity of 1,813.

Clinic, outpatient and dispensary service is complete, and some indication of this provision is evidenced by the fact that there were 204,875 visits made to the hospital outpatient departments, clinics and dispensaries in 1937.

The health service in the public schools is exceptionally well organized, with periodic checkups and complete protection for all pupils. The parochial school system is under the supervision of the city health department, and most of the private schools have reported suitable medical supervision of their students.

Naturally much of the emphasis of recent times has been placed on the care, or lack of it, for the indigent and for the low income group. That this problem exists in our community we all know, but that the medical profession has contributed and is contributing more than its share of the burden of health protection for such groups is evidenced by the facts compiled in this survey.

From the physicians answering the survey forms it has been learned that 16,286 persons were given free services at home, in the office or in the hospital and that 31,022 hours were devoted to the care of free ambulatory patients in outpatient departments, dispensaries and clinics.

This means that each of the doctors answering the survey averaged eighty-five free patients during the year 1937. If we may be allowed to use this figure as a norm it would appear that the physicians in the entire area cared for 10 per cent of the entire population.

tion free, and the part pay group of the low income class, and the indigent group cared for by public welfare departments and state unemployment relief are not included in this 10 per cent. Besides, 135 of the 191 physicians who sent in returns are engaged to some extent in preventive medicine.

At the same time the hospitals report 486,440 patient days of hospital care, and of this number only 41 per cent were pay or part pay patient days—the rest being free patient days or public charges. The city of Providence for the fiscal year ended Sept. 30, 1937, spent \$595,551.46 for expenses at the City Hospital, for maintenance of the city health department, for appropriations for hospitals, for the district nursing association and to one dispensary.

During the fiscal year ended Dec. 31, 1937, the state unemployment relief agency paid \$25,992.05 for hospitalization, \$28,597.62 for medical services and \$7,923.94 for medication.

Such a tabulation would indicate that there is little need for medical care because of refusals to grant such or because of the lack of facilities to provide it. Very few instances were reported of persons seeking medical attention and not receiving it. Such instances were mostly of those persons who refused to accept clinic service or free ward service.

However, two paramount issues were outstanding in the question of medical care need. First, it is apparent that the towns and communities outside the

Providence City area are shirking their duty in not appropriating proper funds for the care of their own indigent who have need to be hospitalized and must be taken to a hospital in the Providence City district. The responsibility for such problems rests with the individual communities, and it is hardly fair to complain against the hospital which refuses such cases, except in an emergency, unless the town accepts its share of the expense burden. Secondly, from school reports, as well as from welfare and similar agencies, there is a strong emphasis on the need for dental care for all classes. The hospital dental clinic in the district necessarily confines its work to minors and thus only partly satisfies the need of the community.

The apparent trouble today is the placing at the door of medicine the health problems arising from economic conditions, and the lack of public education in available health facilities. The decrease in private income has had its subsequent effect on individual health, but the main difficulty lies in the fact that the average individual is reluctant to budget his income, limited though it may be, to include medical service, placing it secondary to luxuries and pleasures. There is also further need for public education in health principles and health facilities of the community. Figures clearly indicate that no person in this area should want for medical attention. However, the public at large needs to be better directed in ways and means to obtain such service.

## OFFICIAL NOTES

### ANNUAL CONGRESS ON INDUSTRIAL HEALTH

*First Annual Meeting held in Chicago Jan. 9 and 10, 1937*

*Continued from page 421*

DR. HARVEY BARTLE, Philadelphia, in the Chair

MONDAY, JANUARY 9—AFTERNOON

#### The Program of the American College of Surgeons in Industry

DR. FREDERIC A. BESIFY, Waukegan, Ill. The American College of Surgeons in June 1926 appointed a Committee on Traumatic Surgery, which selected from its membership a research group, composed chiefly of industrial surgeons and representatives of indemnity companies, to survey conditions in the treatment of accident victims. The committee's report showed that traumatic injuries, in general, were not being cared for by the best qualified surgeons. This condition resulted partly from short sightedness by insurance carriers and by employers, who were considering chiefly the first costs, and partly from lack of interest by the better qualified surgeons in this practice. Unethical procedures were resorted to by some doctors, who were aggressively soliciting this character of work, some of whom were aided by claims adjusters and others who expected rebates from physicians for referring work. The report also showed that the physical well-being of workers and of those injured in industry, in particular, was affected by a strong tendency toward a commercialization of medical service in industry, also that a desire to obtain more experienced surgeons and to use better hospital facilities was being displayed by carriers of workmen's compensation insurance and by large employers of labor.

It became clear that the starting point in a program to assure the best care of the worker and of the injured was not when the surgeon was called or when he began to treat the injury but far before the injury occurred, when control over conditions which might have caused the accident was possible. The first point of attack in an effort to improve conditions, the leaders in

the College program decided, was in industry, where workers were already assembled into groups and where circumstances were forcing employers to assume responsibility for the care of injured workers and sufferers from occupational disease. Investigation of the quality of these services disclosed that conditions were chaotic. It was apparent that the legal and financial factors were occupying a dominant position in the administration of industrial medical service and that the medical factors, which should have been the primary consideration, were often given incidental attention. Early analysis should have shown the employer and the insurance carrier that good medical service would reduce the legal and financial burdens. The College program in industry thus broadened from an attempt to improve the care of the injured workman to include the preservation of the workman's health through prevention of disease and injury. The College drew up a Minimum Standard for Medical Services in Industry, much the same in character as its Minimum Standard for Hospitals. This minimum standard embodied the essential principles which could readily be adapted to any circumstance, and it was welcomed by industry as evidence of the cooperation of the profession in conserving the health and lives of its employees. The five principles of the Minimum Standard for Medical Services in Industry stipulate, in substance, that there should be definite organization of the medical service; a competent medical and surgical staff; adequate records; the use of approved hospitals and medical supervision of all health measures indicated within the industrial organization.

From 1926 to 1933 the College carried forward extensive educational work among employers and physicians in the fundamental principles of supplying proper care to the injured workman. By December 1933 it was possible to publish a list of services which could be classed as approved on the basis of compliance with the minimum standard. This first list bore the names of 518 industrial establishments. Each year since 1933 a new approved list has been issued. The last one, published in October 1936, bore the names of 880 industrial establishments. Since the standardization of medical services in industry depends on voluntary acceptance by the industrial organizations themselves, industry had to be convinced of the advantages of turn-

ing acceptable service. The arguments for economy to be effected through salvaging workmen's lives and capacities to produce had to be presented, with facts and figures to support them. The idea of "safety first" had to be enlarged to include "safety afterward" in order that employers and insurance carriers might appreciate that there was a direct reduction in lost time and in accident compensation costs when the quality of medical service provided was improved. The College was compelled to create in the mind of the employer a different conception than he at first had concerning the place of the doctor in industry. The repairman concept of the physician and surgeon prevailed too strongly in the consideration of this problem by the industrial executive. The difficulty was not lessened by the fact that the employer was taking the doctor at his own estimate, since the profession in general was inclined to look down on the so-called industrial surgeon. It has probably been easier to prove to the employer by research and actual figures showing that good medical service is good business than it has been to attract to industrial medicine and surgery the highest type of physicians. This fact, coupled with the desire of claim adjusters and the personnel directors to run the medical service, is the reason why the medical services were usually subordinate to some other departmental chief. This tendency in organization continued to keep the more able physicians out of industry. This condition has been partially rectified by the insistence in the minimum standard that the physicians on the industrial medical staff have certain qualifications and that the supervision of sanitation of the plant and of all health measures for employees be vested in the physician in charge.

Industry had no generally accepted guide in establishing and conducting medical services until the College formulated its minimum standard and issued a digest which included a plan for organization and an outline of the functions of an industrial medical service. It has been shown that those medical services function most efficiently whose director reports to a major executive, thus assuring a favorable administrative relationship from the standpoint of the physician.

The evils which existed in medical and surgical practice in industry twelve years or more ago have not all been eradicated, but medical departments are much more efficiently run than they used to be and a greater number of more competent physicians are devoting themselves to this type of service. On the whole the worker in the larger plants is now well protected. A grave deficiency still exists in industrial establishments having less than 500 employees, in which 62 per cent of the total number of factory employees work. These establishments do not commonly employ full time industrial surgeons. Conditions are particularly bad in plants which have less than 100 employees, which represent 30 per cent of the factory workers. National Safety Council figures show that in 1936 relative to hours worked there were 62 per cent more lost time injuries in the small plants than in the large ones and that the severity rate was 11 per cent higher in the small plants.

The per capita cost of furnishing medical service to the employee rises sharply as the number of employees decreases so that the plant having 200 or 300 employees or less cannot be expected to maintain its own medical department. The medical profession is obligated to cooperate with industry in devising means of grouping establishments together for service of this kind. The formation of industrial medical services by individual doctors or groups of doctors solves the problem only if arrangements are definitely made for medical supervision within the plants in addition to caring for the sick and injured who visit or are sent to the clinic.

#### Uniformity in Workmen's Compensation Procedure

MR VOYTA WRABETZ, Madison, Wis. The major part of the burden caused by industrial accidents and diseases is an obligation which must be borne by industry. Benefits for disability or death the result of accidents and of occupational diseases arising in the course of employment are the inherent right of workmen. To insure that these benefits will be provided, workmen's compensation laws were enacted and to carry them out a proper administration not merely by the industrial accident boards and commissions but by employers by insurance carriers and by the medical profession is necessary.

Prior to the days of compensation laws recovery for industrial injuries was determined on the principles of the old English

common law. Not only was litigation lengthy and expensive but recovery was doubtful. If a favorable verdict for the employee was obtained, his ultimate recovery was frequently so small that the disabled employee remained a burden on society. The increased use of machinery, the organization of factory production and the increase in employees in one plant made the common law procedure intolerable. To remedy this situation, workmen's compensation laws were enacted.

Uniformity in workmen's compensation laws is desirable, but such uniformity is not absolutely essential and probably not altogether desirable in all aspects. Because of the large area of the United States and of the diversified industries, a different approach to the workmen's compensation problems in particular states is probably justified. At any rate it would be the height of optimism to expect uniform compensation laws in all states.

However, the goal is the same in all the states although the rewards may be unequal and the path not always the same. Uniformity is one feature of workmen's compensation laws which lends itself to ready attainment is adequate medical care and treatment in all its phases.

May I make some observations on what I consider adequate provisions in a compensation law for medical and surgical care? The most important consideration at the time of injury and thereafter is the physical restoration of the disabled employee. The return to full earning capacity is of tremendously greater value to a worker than any amount of compensation benefits that might be paid. It is therefore evident that the medical profession is a controlling factor in a compensation case. The first consideration which the attending physician should give in the treatment of his case is to furnish treatment that is most likely to result in the best possible physical restoration. To this end everything reasonably necessary should be done. It should be the aim of all concerned to rehabilitate the disabled employee to economic and social well-being as rapidly and completely as possible. Limitation in medical and surgical care in either time or money will not accomplish such objectives. It seems almost incredible that a number of states still limit medical benefits to ninety days following the injury and in amounts limited to \$300. In serious cases consultation is desirable. As a part of treatment, curative workshops may be valuable.

No plan can be complete without preemployment and periodic medical examinations. Organized labor has objected to medical examinations which have not been limited to one or more of the following objectives: (a) To place workers in occupations susceptible of being efficiently carried on considering the physical well-being of the examined employee. (b) To place workers in occupations where physical or mental handicaps will not constitute a hazard to themselves, their fellow employees or the public. (c) To place workers in occupations where physical handicaps will not constitute a continuous hazard to the physical property of the employer or fellow workers. (d) To eliminate from employment applicants or workers with contagious or communicable diseases.

An examination program designed solely to select only those with a high degree of physical fitness or for mere medical defense against possible claims is against public policy. Many occupational diseases can never be successfully controlled without proper medical examinations of all exposed persons and of all those who are to enter service in work entailing the breathing of deleterious dusts or fumes. Representatives of organized labor favor a properly designed physical examination program. We are working on such a plan in Wisconsin through a committee representing industry and labor assisted by a special committee of physicians. When adopted, it will provide for the placement of employees in work commensurate with their health will safeguard them against accidents and diseases to which they might be more prone and will provide an adequate system of medical control of accidents and diseases as a necessary supplement to engineering control. On the other hand it will provide against oppressive examinations and against the improper use of the information obtained through such examinations. As a whole it will permit the early treatment of diseases caused by occupational exposure and lead to the discovery of such diseases and their causes. It will reduce the cost of labor turnover and of absenteeism and produce happier and more efficient workers.

In the satisfactory disposition of most compensation cases the attending physician has an important role. This is par-

ticularly true at the end of the healing period and in the final determination of questions of permanent disability. The physician should always have this critical time in mind in the treatment of his patient. To meet this crisis the attending physician must gain the confidence of the patient. When an injured employee returns to work, the physician has two definite obligations. The first is to the injured employee, who should be advised of the class of work he is able to do and more particularly of the kinds of work he should refrain from doing. The physician's second duty is to give the same instructions to the employer either directly or through a representative of the insurance carrier. The foreman should be impressed with the fact that the injured employee still has physical handicaps which may limit his efficiency and that only through patience will his rehabilitation be successful.

It may not be out of place for a layman to give a word of caution on the handling of cases involving emotional instability. Neurosis almost always represents a difficult and pitiable condition. Often it is brought about by some indiscreet suggestion, perhaps even by attending physicians. The compensation law provides for the payment of compensation not only during the period of temporary total disability but also for permanent disability in the determination of which all interested parties must depend on the opinion of the physician. The compensation law aims to give to the injured employee adequate compensation for the disability occasioned by injury. When this question is being considered, the surgeon should not forget that he is still the physician of a particular patient and in estimating disabilities should never take into account the fact that he is being paid for his services by the employer or insurer. May I suggest that the surgeon should not be too sanguine in judging the results of his work. The results may have been the best obtainable but it does not follow that an injured member has been restored to perfect normality. The surgeon should be particularly alert therefore to be fair in appraising the disability. Physicians should become thoroughly familiar with the compensation law of their state and with its administration, so that their reports and opinions convey a proper meaning. In estimating disabilities the surgeon should never take into account the amount of money which is to be paid. "Let the chips fall where they may." Estimates of disability should not be predicted but should be determined scientifically after maximum recovery has been attained. The schedules contained in most compensation laws usually include amputations and the loss of vision and hearing. Any injury short of amputation is compensated for on the basis of a relative loss, that is, the loss is estimated as a certain percentage of the allowance contained in the schedule for the next greater rated disability. For instance, a disability limited to the function of the forearm from the elbow to the tips of the fingers is comparable to the loss of an arm at the elbow and not to the loss of an arm at the shoulder. Within limitations, it is possible to establish by custom or rule the related disability applicable to a given handicap. The Industrial Commission of Wisconsin, after many hearings in cooperation with the state medical society, adopted a schedule of related disabilities to serve as a guide. For example limitation of active elevation of the arm in all directions to 90 degrees, but otherwise normal, is a loss of 20 per cent of the arm at the shoulder. If other conditions exist, the percentage of disability varies more or less as the disability varies from this standard.

Workmen have complained that doctors whose bills are paid by employers or insurance companies have discriminated unfairly against the workmen in underestimating the degree of disabilities. Contrary complaints are made by employers against doctors who are retained by workers. After years of experience and seeing probably as many actual cases as any one physician may see, it would be strange if those who administer compensation laws did not have some fairly good ideas as to how disabilities should be measured. It is soon discovered whether or not a physician is giving that unbiased study which enables him to estimate disabilities fairly. Members of the medical profession usually give honest judgments as to disabilities and their estimates of disabilities are usually accurate and in agreement with one another.

The question whether or not the disability is the result of accident or occupational disease offers more difficulty. There are still many problems which medicine has not solved and the cause and effect are still controversial. Opinions based purely on conjecture have no probative force. The scientist in any given set of facts will always give the reasonable probabilities from which a determination can be made. Fancy theories that a condition is not the result of a definite injury in the face of a definite chain of events or that a disability may be due to injury when more reasonable causative factors are present are of no particular value in the determination of medical questions. However, difference of opinion should never degenerate into partisanship, for then the physician ceases to be impartial and the value of his service in the administration of workmen's compensation laws becomes practically nil. For the determining of medical issues, either as a witness or when appointed to make independent examinations, the members of an old and honored profession should always give opinions independent of their source of employment and purely on the reasonable scientific probabilities applicable to the given situation. The whole success of compensation legislation depends on him and the future well-being of thousands of men injured each year depends on his skill and his judgment. It is to the credit of the medical profession that compensation laws have generally worked out as successfully as they have. But it is desirable that the profession weed out its undesirable members and so far as the compensation laws are concerned give that quality of judgment and attitude which will gain the fullest confidence of injured men and render to employees and employers uniformly impartial service.

#### The Basis for Cooperation Between Insurance Companies and the Physician in Industry

MR AMBROSE B KELLY, Chicago. The question of medical care for those in the lower income brackets is much before the public, yet it is seldom remembered that the working population in all states but two is provided with medical care for injury or disease arising out of employment. More than 700,000 persons received such medical attention annually at a cost of more than \$25,000,000. The insurance companies furnish the organization through which the funds to make such payments are collected from industry and they supervise these medical expenditures. I come before you as a representative of one branch of the medical profession's largest single customer, the compensation insurance companies. Let us determine the objective and the procedures of the insurance company handling workmen's compensation coverage to find a basis for cooperation with the physician.

Under the workmen's compensation acts the employer is responsible for any injury and in some cases any occupational disease suffered by his employees in the course of and arising out of their employment. The law requires the employer to guarantee that this obligation will be carried out either by furnishing evidence of insurance in an admitted company or by establishing his own ability to act as a self insurer.

The employer makes a contract with an insurance company under which, in return for a premium, it assumes his statutory obligations. Acting for the employer, the insurance company is generally required to pay a stated scale of benefits in the event that injury or disease disables the worker and also provide medical service to those injured or disabled within the qualifications set forth in the law. Since most compensation acts provide a waiting period ranging from a few days to a few weeks before benefits are paid, there are hundreds of thousands of cases in which the medical expense of treating a slight injury is the only expenditure made by the insurance company as the result of an accident. In more serious cases the medical and hospital expense of a single individual often amounts to thousands of dollars. The percentage of the compensation payments which is used for medical care is constantly growing. Under current conditions the amount paid for medical service is a considerable part of the total expenditures made by the compensation carrier. The premium charged the employer is regarded by him as one of the items of operation expense and is passed on to the ultimate consumer of his product as a part of its price. Employers anxious to hold down compensation costs have been paying close attention to the rise in medical cost.

The compensation carrier gives the employer all possible assistance in a safety campaign designed to prevent accidents or occupational disease, provides adequate medical care and treatment for those injured or sick from occupational disease and pays any benefits due to the employee under the act. In the event of disagreement between the adjuster, representing the insurance carrier, and the employee as to the extent or existence of disability or as to whether the injury received was within the protection afforded by the compensation act, machinery is provided for a hearing and a determination of the disputed question, with expert medical testimony introduced by both parties.

At every step in this program the compensation carrier depends on the experience and ability of doctors for advice and service.

In most states the employer required to furnish medical service has the right to choose the physician, with qualification that in an emergency the employee may choose his own physician and hospital and, of course, he may do so when the employer has refused to provide medical service on demand. When the employer is insured, he looks to the insurance carrier for advice with reference to the name of a doctor to handle injuries. The insurance carrier is guided by the following considerations: 1 The doctors chosen must not only be competent and of good reputation but must have had experience in the type of case which will probably arise out of the plant. 2 It is desirable that the doctor have a properly equipped office with some one available at all times, convenient to the insured plant. 3 He should be in constant touch with all developments in the field of industrial surgery, particularly the field of rehabilitation. 4 He should be familiar with the workmen's compensation law of his state and be in a position to prepare the various forms and reports required. 5 He must be willing to call on specialists for consultation.

The medical profession can be proud of the service which the injured workman receives under the compensation acts. A survey, made a few months ago, disclosed that competent doctors were doing industrial work from coast to coast. With the exception of a few rural areas where the volume of industrial practice was not sufficient to provide experience and justify special study, our companies reported that they were satisfied with the service rendered. It is interesting that the bulk of this service has been and will be rendered by general practitioners, with the industrial specialist confined to the metropolitan areas. This record made over a period of twenty-five years, demonstrates that the medical profession has the ability to handle a problem of real social significance without any sacrifice of the basic principles on which the profession has been built. However, improvement is not only possible but necessary and, since the objective of better medical care to the patient is common to both doctors and insurance companies, cooperation between them is natural and should be effective.

Comparatively little attention is given to industrial medicine and surgery in our leading medical schools. The almost complete lack of graduate instruction is deplorable. It is hoped that the growing recognition of the importance of industrial medicine, of which the Council on Industrial Health and this congress are sufficient proof, will soon be felt in the field of medical education. A harder problem is the necessity of providing facilities for keeping practicing physicians in touch with new developments in the field of industrial medicine. Too often it seems to us from the sidelines, the large place of industrial practice in the medical picture is not realized when programs and clinics are being arranged. Any comprehensive program which might be developed by the Council on Industrial Health and placed in effect by the state and county medical societies will have the enthusiastic support of the insurance companies.

The greatest single cause of friction between the insurance companies and the medical profession is the controversy over the selection of the doctor to treat the employee. Under the workmen's compensation acts of thirty-nine states the responsibility for providing medical service and the right to select the physician who shall render that service are given jointly to the employer and to his insurance company. This has sometimes resulted in an attempt by either self-insured employers or insurance companies to concentrate all their industrial medical work in the hands of a few doctors, and occasionally clinics have been set up to handle industrial cases on a mass production low cost basis. In consequence there has been agitation against any inter-

ference by the employer with the selection of the physician, by the employee, and the legislatures of a number of states have considered bills which would give to the employee "free choice" of doctors. Such measures, although generally introduced at the request of local or state medical societies, have often secured labor support and such groups as chiropractors and osteopaths are always enthusiastically behind them.

There is a growing realization on the part of many insurance companies that an undue concentration of industrial work is undesirable. It is conceded by claims men everywhere that the doctor in general practice is fully competent to handle much of the medical service which arises from compensable injuries and there is a growing feeling that an employee who has gone to his own physician for treatment of a compensation injury should continue under the care of that doctor unless there are complications which take the case out of his experience and make consultation or a change in doctors necessary. The practice of indiscriminate "lifting of cases" from the hands of able doctors so that they may be treated at lower cost per visit by other physicians is generally condemned by the insurance companies and within a short time it should cease to be a problem. Even though it is admitted that there is room for improvement in the methods of the insurance companies, they have opposed unlimited free choice because of their conviction that it lowers the quality of medical service rendered to the injured person. Free choice will continue to be opposed until a plan can be worked out under which the insurance companies will feel reasonably sure that the doctors handling industrial cases will be skilled, experienced men. Work on such plans is going forward now. A cause of friction is the problem of determining the proper fee for a doctor who has treated a compensation case. In a few states an attempt has been made to handle the situation by enacting a statute which gives the industrial commission or some other body the power to set up a fee schedule. The insurance companies regard a rigid fee schedule as objectionable, because the very nature of medical service would seem to require that the charge correspond with the ability, the experience and the service which were required in an individual case. Under a fixed fee schedule the same standardized amount will be paid to a capable doctor who has secured an excellent result and to another doctor of less skill who has secured an unsatisfactory result. The medical profession seems to agree that a standardized fee schedule would be undesirable in general practice and the insurance companies feel that the same reasoning is entirely applicable in industrial medicine.

It has been proved again and again and in every section of the country that there is no issue now in controversy between the medical profession and the insurance companies which will not yield when attacked by conference committees representing both groups. It has been my pleasure to take part in many such conferences and invariably an answer satisfactory to both groups has been found. The medical profession will find the insurance companies always ready to consider with them any problem in which the two are jointly concerned, from a national question to the smallest local dispute. I think that, on behalf of the insurance companies, I can pledge our willingness to go more than half way in adjusting any situation which is of present concern.

The true basis for cooperation between insurance companies writing workmen's compensation insurance and the physician in industry lies in their joint determination to bring about the recovery of the patient in the shortest possible time with the best possible result. The insurance companies will support in every way in which they can every effort of the medical profession that is aimed at bettering the quality of medical care in compensation cases. It is inconceivable that we should not join hands in a cooperative program which will establish a quality of medical service far above that now reached and demonstrate the ability of medicine and industry to handle a problem of this scope and significance with an efficiency attainable in no other way.

#### A Program for Committees on Industrial Health in the State Medical Societies

DR A D LAZARUS, Baltimore. This is an industrial nation. The huge population which makes its living in mechanical and manufacturing pursuits is exposed to many environmental factors in places of employment inimical to health. There are more

than 900 occupational exposures to toxic substances and conditions that may impair the health of the worker. Disabling illness is 76 per cent higher among nonskilled labor than in the so-called nonindustrial group and the death rates are 24 per cent higher in the former than in the latter. True, not all of the disease and death in this class of the population is due to occupational conditions. Much is due to ailments that are the heritage of mankind. The health of the industrial worker is precious to him and to society is a direct responsibility of the medical profession and has been neglected in the past by both the industrialist and the profession. The leadership in industrial health conservation which should have been assumed long since by the medical profession is now being usurped by the industrialist. The time has come when the organized medical profession must manifest a constructive interest in the problems of industrial health, must realize their fundamental importance and must actually do something about it or else relinquish leadership to industry.

What must the state medical society do to capture the position and responsibility that rightfully belongs to the physician? Conditions vary so in the various states that a cut and dried program is impossible. The industrial physician is primarily a diagnostician, a sanitarian, a man highly versatile in medicine and in the industry he serves. He is a therapist only secondarily. It is his task to appraise the physical quality of the working personnel, to see through his own knowledge of the various jobs and men available that jobs and men are suitably matched, that neither may suffer through the shortcomings of the other, to discover toxic substances, fumes and vapors, to instruct the engineers in their avenues of entrance into and exit from the body, their effect on the body in their passage through and their residence within and assist in creating means for their exclusion from the vulnerable zone of the worker. The industrial physician must study the sanitation of the plant, the lighting, ventilating, heating, cleanliness, fatigue, monotony and all those environmental conditions that go for the promotion of health and efficiency. The problem of absenteeism, discovery of its causes and removing them with the aid of the family physician are an important phase of his work. He must take an active part in programs of accident prevention, health education and environmental improvement, and in various local activities that may be created for the maintenance of good morale and good physical and mental hygiene. In activities such as these, the industrial physician has not encroached in the least on the rightful preserves of the private practitioner.

Perhaps the first task that confronts the state medical society in meeting this challenge is a realization of the ignorance that exists in medical circles concerning the problem of occupational diseases. We have no real statistics on the actual prevalence of occupational disease in this country, even though in many states such diseases are reportable under the law. Let us acknowledge honestly that this situation exists not because physicians merely overlook the legal requirements for reporting such cases but because they all too often actually fail to recognize them.

We cannot ignore the cry that the medical curriculum is overcrowded and that there is no time for the teaching of industrial hygiene even as an elective subject to undergraduate students. Possibly the best we can hope from the medical schools for the present in teaching is emphasis on the occupation of the patient in history taking and general diagnosis, and the showing of cases of industrial diseases as they appear in the wards and clinics. It is certainly not too much to ask that faculties of medicine at least give undergraduate students an awareness that occupation and disease are often closely related. It is hoped that teaching hospitals in industrial centers may, as interest develops and realization deepens, establish beds, outpatient and laboratory facilities for the adequate study and treatment of industrial diseases. This needs the sustained interest of the organized profession.

Social advance has reached the point where diseases due to specific occupational exposures are being placed in the almost identical category with industrial injuries. The physician can no longer remain in ignorance of those diseases and do honor to his calling. The medical society meeting is the proper place to which the general practitioner should turn for acquisition of knowledge and the stimulating of interest in new and timely

subjects. I urge the development of programs and symposiums dealing with industrial medicine. Too frequently the occasional industrial program given by the average medical society tends to lay undue emphasis on the surgical or economic angles of the problem. We must focus our interest on man the worker and on all the forces, chemical, physical, mental and spiritual, that may tend to affect him adversely.

Perhaps the fundamental function of the physician is as a teacher. Prevention of disease, as the true basis of medical practice, receives its primary impetus through education. To whom then should the industrialist, who is responsible for plant environmental conditions, turn for knowledge? The only answer is to the medical profession through its organized bodies. Industry has taken the initiative in many instances, and much of the constructive work dealing with industrial health conservation has originated not in medical circles but in business itself. Let us establish cordial relations with associations of commerce, trade and labor groups, manufacturing associations and insurance groups so that we may better function in our fundamental role as teacher. I suggest the sponsorship of joint meetings with such groups, that problems of mutual interest dealing with occupational disease, accident prevention and industrial hygiene may be discussed.

There is a definite place for the doctor in every industrial plant, large and small, in an important capacity. Until industry and labor are taught to recognize that place and until the actual cash value of intelligent health conservation is demonstrated comparatively little progress can be made. The task is ours. Let us not overlook the need in small industry for medical guidance. Of the manufacturing establishments of this country 80 per cent employ less than 100 persons and about one fifth of our industrial population is employed in such establishments.

Perhaps the local medical society is the place where organized courses in industrial medical problems might be given for interested physicians, especially younger men. Even though the participants in such courses may never establish definite relationships with industry, the knowledge gained and the visits that would be paid to manufacturing plants should broaden points of view and sharpen diagnostic acumen.

In most of the states, workmen's compensation laws have arisen to replace the old common law relations of master and servant in injuries of occupation. From their very onset they involved changes in methods and philosophies of medical practice, in physician and patient relationships and in methods of remuneration for professional services. The approach of the new law has seemed stealthy only because the organized medical profession slumbered. Partly as a result of this indifference workmen's compensation neither started nor developed as auspiciously as might have been the case had the more thoughtful minds in medicine been interested. At the outset the regulation of the medical aspects of the law was placed in the hands of lay industrial commissioners, lay insurance adjusters and a substratum of the medical profession more interested in personal gain than in scientific or humanitarian excellence. This situation has not been fully eradicated. However, relations under the various workmen's compensation acts have improved vastly in the last decade. There seems to be a renaissance of interest in industrial injuries and diseases by the better qualified in medicine and the injured worker is the beneficiary.

The study of social legislation such as workmen's compensation laws should engage almost every state medical society. Investigations of workmen's compensation laws have been undertaken by medical groups. Some have been fruitful but most have been futile and some even ridiculous. The error has usually been fundamental ignorance on the part of the investigators of the philosophy back of these laws. A study of existing laws should be undertaken in singleness of purpose and sincerity of heart. The purpose should be the physical and social well-being of the industrial worker and his influence on the rest of society.

The question of free choice of doctor in cases of industrial injury is worthy of careful but objective study by organized medicine. The judgment of medical investigators here may be tempered by prejudice or tradition, for there is much in the philosophy of workmen's compensation that is contrary to past experience. Points of view may be unconsciously distorted by thwarted personal desires to participate to a larger

extent in the surgery of industry and to share in the financial rewards. Passions may have been aroused by apparently unwarranted acts of unfairness by insurance adjusters or plant executives. Our problem must be, however, a dispassionate, informed, reasonable study of the existing laws, with their social and economic backgrounds, and the reasons for certain techniques that have developed in their administration. We must never lose sight of the party of prime interest, the injured worker. This is a workmen's compensation law. It is not a doctor's compensation law, an employer's compensation law or an insurance company's compensation law.

It is possible that in certain states, injured employees can to advantage be given free choice of doctor. In other states, circumstances may be such that greater limitations are necessary to assure competent and prompt surgical care of injured men. It is my belief, based on observations extending over many years, that the finest surgical care is not received by the industrially injured under a system permitting unrestricted free choice of doctor. I realize fully the abuses under the system delegating the choice of physician to the employer or his insurance company, however, if this choice be motivated by the highest ideals the abuses are fewer and the final results in human suffering and wastage infinitely smaller than if the worker is free to go his way unguided. It is most probable that an effective compromise could be had, however, by the development as between medicine and insurance of statewide programs of cooperation where a much wider and freer choice of doctor could be allowed the injured worker.

In all parts of the country, existing workmen's compensation laws have been or are in process of being extended to cover occupational disease as well as injury. Let us not overlook the profound influence that such legislation may have on medical practice. By legal enactment such laws may often be extended to include all the ailments to which mankind is heir. Proper though it is to impose on industry the burdens of those physical ills that industry inflicts, it is not socially sound to thrust on industry the entire health problem of society or even a substantial part of it. This is not good for society in general or for the physician in particular. I suggest that the local medical society scrutinize closely all such pending or existing social laws.

Workmen's compensation administration involves the payment of variable cash benefits for varying degrees of disability and creates generous opportunity for differences of medical opinion not merely as to degrees of disability but as to causal relationships between injuries and disabilities. This requires the frequent attendance of the physician before judicial or quasijudicial bodies. One expects differences of opinion to exist with honesty between physicians but one does not expect such absolutely variable opinions on such relatively simple issues as are not infrequently heard in legal controversy today. Let our local medical societies turn the light of publicity and condemnation on the few of its members who are willing to sell their priceless birthright for a mess of pottage. In workmen's compensation matters fulfillment would not be possible without the application of the insurance principle in some form. It seems certain, however that medicine and insurance must lie down together in the same pasture. It seems logical that a common meeting ground be sought, a place where points of view can be clarified understood and reconciled where objectives can be unified where sympathetic cooperation can be created. I suggest the conference table as the place to seek these happy ends. Insurance is administered by reasonable men, just as is medicine. The state medical society will find it worth while to maintain close contact with local insurance organizations, claim associations and similar lay groups. Such a contact will do much to eliminate the abuses which often occur in both sides. We must acknowledge that the doctor is not always blameless. Abuses and exploitation usually melt when subjected to illumination. When they do not, legislation with medical sponsorship must be adopted.

I urge on us the need for an aggressive policy in approaching the problems of health in industry. It is for us to take the initiative in making constructive advances lest they be thrust on us under the leadership of industrialists, chemists and welfare workers. Let us recognize our responsibilities.

establish an enlightened point of view and do our part with a singleness of purpose in the full knowledge and realization that we, as a profession can advance and prosper only as society advances and prospers.

#### DISCUSSION

DR H. H. KESSLER, Newark, N. J. I should like to endorse the remarks made by Mr. Wrabetz. There are many difficulties which face the physically handicapped individual and one of those is that there are only twelve or thirteen compensation laws that include artificial limbs in their requirements for medical and surgical care. Another question is that of uniformity and the determination of permanent disability as end results of industrial accidents. We use the word 'scientific' loosely. Perhaps there are scientific methods we might apply to estimate disability, and in the eye and ear they are easier of achievement. With the rest of the body I find it difficult. It is very difficult to determine a man's capacity to work and to define what his functional limitations are. I once certified a man as totally and permanently disabled. He, an iron worker, fell from a height, sustaining a fracture of the spine, with cord injury and spastic paraplegia. He returned to me five years later with a spastic gait, without the aid of canes, and said 'I am looking for a job as a structural iron worker.' He had credentials to indicate that he had been employed as a structural iron worker following his accident. He had worked for one employer who knew what his capacities and limitations were.

MR E. T. BUCKINGHAM, Bridgeport, Conn. In Connecticut the doctors complain that the reports they have to make out are very complex. Has any attempt been made to simplify the reports the doctor has to make to the insurance carrier?

MR AMBROSE B. KELLY, Chicago. The question of the forms to be used in making medical reports has been considered by a committee of the National Council on Compensation Insurance, which has attempted to secure uniformity throughout the United States in the medical reports used. If the present reports are of concern because of their complexity, the situation might be considered with the committee of the national council, which would be receptive to suggestions with reference to the simplification of reports. The insurance business is essentially a paper business, built on files, reports and forms. The people in the business realize the desirability of keeping the forms as simple as they can, provided the basic information which we must have either to satisfy the administrative body which is handling the compensation act or to prepare the necessary statistics of our own office is provided.

DR A. S. LEVEN, Chicago. With reference to the economic situation, I think the controversy arises not only from the fact that the insurance companies have the privilege, which is justly theirs, of assigning the various physicians in the respective territories to the various companies but also from the point of view of the medical bills. The organized physician in industry today is a much underpaid man, whether or not today medicine is a competitive system. But no matter how good you are or how bad you are, you compete with the next fellow—and this is where the point comes in. The insurance company and the firm are there for a purpose which is to make as much profit as possible and the doctor gets it in the neck.

MR KELLY. The contacts that we have made with the medical profession in the past year would seem to indicate that much of our trouble arises from the lack of contact between the doctor and the insurance company's representatives. We have criticized the representatives of the companies whom I represent for their lack of a sympathetic understanding of the problems faced by the doctors in their field and we hope they will take more interest in your problems and work closer with you. At all times here we have two large groups—both sincere, both with definite social objectives which they are doing their best to attain—who can get much further if they work together. If we admit from the beginning that we are honest on both sides that we are sincere that we are trying to do a good job and sit down together to consider our respective problems we shall find that those which seem difficult are not so hard after all.

MR MARSHALL DAWSON, Washington, D. C. The employers and insurance carriers and the compensation administrations of the United States have been pretty well sold on the possibility of great savings through the engineering phases of accident prevention, but the state administrations are almost unaware of the vast savings in costs that can be effected through an improved type of medical care. So far as I have learned, there is almost a complete dearth of statistical information in the offices of the state compensation administrations that would enable the state administrators to check on the competence of medical care. I am speaking now of a statistical check. I hope you will encourage the state compensation administrations to collect more data relating to the type and quality of medical care of workers, especially relating to end results, a thing which will enable the compensation administrators to have a fairly correct idea of what results should be expected in treatment especially as measured by the duration of temporary disability. In reading the publications of the American College of Surgeons, I inferred that because of the great progress in surgical operative methods during the last fifteen years there has been a marked reduction in the periods of temporary disability, which would be found in certain types of disabilities, in what we call temporary or total compensation, and the temporary disability preceding permanent disability. The publications of the College of Surgeons indicate that the period of temporary disability has been reduced, but the compensation reports of the state of New York indicate that from 1932 to 1936 the duration of temporary disability increased. From one point of view this would indicate that medical science and practice are going backward rapidly. Compensation administrators can explain this situation to a certain degree but with all due allowance for the reluctance of workmen to say they are cured when they have no jobs to return to, this thing ought not to be. If any of you have information indicating either progress or retrogression in the average duration of temporary disability, I should much like to get it.

DR O. J. LA BARGE, Salt Lake City. I came here as the chairman of the Section on Industrial Hygiene of the Utah State Medical Association. In Utah, aside from self insurers, the patient has the right to choose his own physician and we have a fee schedule. During the last five sessions of the legislature we fought the self insurers on that proposition. We found that the choice of a physician or the employer's choice of a physician was often predicated on the recommendations made by the field agents of the insuring companies. We have some pretty big families in Utah. It is remarkable how often Brother Jim or Cousin Bill is the best doctor in the community and succeeds in getting all the industrial work. We have a committee of the state medical association that

cooperates with the state insurance fund. If bills come in that seem excessive, they go to the advisory committee, and the advisory committee has authority to recommend a cut. Also if patients do not seem to be getting along as well as they could, the advisory committee of the state medical association can advise consultation or can transfer the patient from one physician to another. It has worked well, and we believe our fee schedule has maintained the economic status of the physician. We are getting case per case, at least 25 per cent more than our brother physicians in the great state of California, where the self insurers and the carriers choose the physician. It is out of place to adopt a selfish attitude. We all ought to be unselfish but I fully believe the medical association has to look out for their economic welfare in a changing world.

DR A. D. LAZENBY, Baltimore. Beyond thanking the gentlemen who discussed my paper, I advocate nothing except study, dispassionate, free honest study of all facts that are available. If we will approach that study from the standpoint not of having our local medical society the best paid in the country but from the standpoint of having our injured workers the best treated in the country, I think our study will probably be more fruitful. (To be continued)

### RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company, entitled "Your Health," began Wednesday October 19 and will run consecutively for thirty-six weeks. The program is broadcast each Wednesday over the blue network of the National Broadcasting Company at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).<sup>1</sup>

These programs are broadcast on what is known in radio as a sustaining basis, that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the program at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

February 15	Healthy Hearts
February 22	Cancer Can Be Cured
March 1	Diabetes

1. Owing to program conflicts there will be no Chicago broadcast of the network program. Instead a recording of the program will be broadcast over station WGN at 8 p. m. each Wednesday. This recording will be an identical rebroadcast of the network program broadcast earlier the same day.

## GRADUATE MEDICAL EDUCATION: ARKANSAS

A PROGRESS REPORT OF THE FIELD STUDY ON GRADUATE MEDICAL EDUCATION IN THE UNITED STATES  
BEING CONDUCTED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

In 1936 the Arkansas Medical Society began a semiannual two day course of postgraduate instruction in Little Rock. The state society's committee on postgraduate study was formed with Dr. D. A. Rhinehart as chairman and fourteen other members from various parts of the state. This committee invites from two to four out of state speakers to participate in each session. Arkansas physicians supplement guest speakers on the program. Lectures and round table discussions of not more than two general subjects of medicine feature each meeting. The facilities of the University of Arkansas School of Medicine are placed at the disposal of the state medical society. A registration fee of \$5 is charged to provide travel expenses for guest speakers. Announcements are sent to every member of the state medical society and to the secretaries of county medical societies.

In 1936 pneumonia and heart disease were considered. One hundred and forty-nine practicing physicians registered. In January 1937 the medical and surgical aspects of gastroenterology were discussed. Eighty-three physicians were in

attendance. In September 1937 gynecology and fractures featured the program and the attendance totaled eighty-four physicians. The fourth session, held in January 1938, was devoted to pediatrics and genito-urinary disease, with a total registration of 113. In October 1938 the recent advances in medicine were emphasized. At this meeting patients were shown and the attendance totaled 128 physicians.

Beginning in January 1937 the Arkansas Medical Society and the Arkansas State Board of Health sponsored a series of six consecutive lectures in obstetrics in six cities of the state. An out of state physician was employed as instructor with funds provided by the Children's Bureau of the United States Department of Labor. The state society's special committee on child and maternal welfare was composed of fifteen members and represented the profession in the various parts of the state. This committee planned the itinerary of the instructor. Announcements were prepared by the secretary of the state medical society and mailed to all physicians in Arkansas. Approximately 200

attended the illustrated lectures, which were held usually in civic buildings. In each town the local member of the maternal and child welfare committee was responsible for publicity and local arrangements.

In May and June 1938 a similar series of six lectures and clinics in pediatrics were held in six towns. Again an out of state physician was engaged, but in this course the instructor visited each town once a week and spent the afternoon and evening so that cases might be presented and round table discussions might be held. Two hundred physicians registered with the secretary of the state medical society for this course. Notices

appeared in the state medical journal and announcements were made as for the previous series.

One month courses in the venereal diseases have been sponsored and financed by the state board of health at the United States Public Health Service Venereal Disease Clinic at Hot Springs, Ark. One physician is selected in each county of the state by the respective county medical society. His travel expense is paid, in addition to a stipend of \$150 or \$200 a month.

There are 1,850 physicians in Arkansas, 1,032 of whom are members of the Arkansas Medical Society.

## LEGISLATION OF INTEREST TO PHYSICIANS CONSIDERED BY STATE LEGISLATURES IN 1938

*Prepared by T. V. McDavitt of the Bureau of Legal Medicine and Legislation*

This survey attempts to report as briefly as possible what are deemed to be the more significant legislative proposals considered by state legislatures in 1938<sup>1</sup>—significant from the standpoint of public health and the medical profession. As will be noted, not only are actual enactments enumerated in a more or less arbitrary arrangement of subjects and topics but discussion is also made of bills that did not become law. To expedite perusal for those more interested in ascertaining what the legislatures have perpetrated in the name of legislation than what could have been or may in the future be, enactments are printed in larger (ten point) type while proposals failing of enactment and footnotes are printed in the usual type of the survey (eight point and six point).

### I. LEGISLATION RELATING TO LICENSES TO PRACTICE THE HEALING ART

#### A. Legislation with Respect to Corporate Practice

**HOSPITAL SERVICE PLANS**—Laws were enacted in Kentucky<sup>2</sup> and New Jersey<sup>3</sup> authorizing the formation of corporations to provide on a so-called "non-profit basis" "hospital care" to their members or subscribers. The activities of such corporations under these laws would seem to be limited to the rendition of hospital care and not to include medical or surgical care. A new Louisiana law<sup>4</sup> provides for the formation of so-called service companies, authorized to make agreements with members or subscribers to furnish hospitalization and incidental drugs on the occurrence of sickness or other physical disability of a member or subscriber. Whether such companies may also contract to furnish medical care is not clear from a perusal of the law.

An unsuccessful attempt was made in South Carolina<sup>5</sup> to permit hospital members of the South Carolina hospital association to operate hospital service plans on an insurance basis.

An unsuccessful attempt was made in Mississippi<sup>6</sup> to amend the Mississippi law permitting persons, associations or corporations to engage in the business of making contracts in advance of sickness or illness to furnish or pay for hospitalization so as to permit such firms, associations or corporations also to contract to furnish or pay for medical and surgical service.

Two bills were killed in Mississippi<sup>7</sup> which proposed to prohibit a corporation operating a hospital department for its employees and making deductions from their pay to cover medical and hospital services, from contracting with a particular physician or hospital for the rendition of such services without a favorable referendum vote of the employers.

**CORPORATE PRACTICE IN GENERAL**—A bill considered in New Jersey<sup>8</sup> which was not enacted, proposed, among other things, specifically to prohibit the corporate practice of medicine but to legalize such practice by (1) a corporate employer in connection with the treatment of employees injured in the course of their employment or in examining applicants for employment, (2) an educational corporation in the rendering of medical care to and examination of pupils, and (3) an insurance corporation in examining applicants for insurance.

#### B. Changes in Medical Practice Acts Affecting Nonsectarian Practitioners

**BOARDS OF MEDICAL EXAMINERS**—The Massachusetts legislature rejected a proposal<sup>9</sup> to eliminate the requirement in the medical practice act that not more than three members of the board of registration in medicine shall be members of any one chartered state medical society.

**CONDITIONS PRECEDENT TO LICENSURE—Educational Qualifications**—A law enacted in Massachusetts in 1936,<sup>10</sup> to become effective in 1939, requires every applicant for a license to practice the healing art to have completed two years of premedical collegiate work and to have graduated from a chartered medical school approved by the secretary of the board of registration in medicine, the commissioner of education and the commissioner of public health. A new law adopted this year<sup>11</sup> postpones until Jan. 1, 1942, the effective date of the 1936 law.

Two attempts to nullify the effects of the 1936 law failed of enactment.<sup>12</sup> These proposals sought to require the board of registration to examine any applicant who had obtained a degree from any medical college authorized by Massachusetts to confer degrees.

Two laws were enacted in New Jersey<sup>13</sup> which seem to permit particular individuals without meeting the educational qualifications required of other applicants to be examined for licenses to practice medicine. One of these laws<sup>14</sup> authorizes the board of medical examiners to examine any person who has matriculated at a

<sup>1</sup> During 1938 the legislatures of Kentucky, Louisiana, Massachusetts, Mississippi, New Jersey, New York, Rhode Island, South Carolina and Virginia met in regular sessions. In addition there were one or more special sessions of the legislatures of Arizona, Arkansas, California, Georgia, Illinois, Indiana, Kansas, Kentucky, Massachusetts, Michigan, Mississippi, New Mexico, North Carolina, Ohio and Pennsylvania. Altogether there were a total of twenty-eight legislative sessions.

<sup>12</sup> Mass. H. 1195 H. 1341.

<sup>13</sup> N. J. Laws 1938 c. 121 and c. 144.

<sup>14</sup> N. J. Laws 1938 c. 121.

legally chartered medical college in the United States now in good standing, has therein attended four full courses of lectures over four years, has completed an eighteen months internship in an approved hospital in the state and has thereafter continued to serve at least fifteen years as a resident member of the staff of an approved hospital in the state. The other law<sup>15</sup> requires the board of medical examiners to examine for a license to practice medicine and surgery any person more than 21 years of age, of good moral character, a citizen of the United States and a resident of the state, who has graduated from an approved high school, subsequently completed a four year course in a college or school of arts and sciences approved by the commissioner of education, has subsequently completed a four year course of study in a legally incorporated medical or professional college, receiving therefrom the degree of Doctor of Medicine, has subsequently served as an intern for at least one year in a hospital approved by the board, and has been licensed by the medical licensing board of another state of the United States.

**Citizenship Requirements.**—Bills were killed in New York<sup>16</sup> to limit licensure to citizens of the United States or to persons who had declared their intention of becoming citizens.

**Revocation and Suspension.**—*Causes.*—Laws were enacted in Mississippi<sup>17</sup> and New York<sup>18</sup> setting out causes for the revocation, suspension or refusal of licenses in addition to the causes stated in the medical practice acts prior to the enactment of the laws in question. The new Mississippi law<sup>17</sup> adds the following causes: the habitual personal use of a narcotic drug, administering, dispensing or prescribing any narcotic drug otherwise than in the course of legitimate professional practice and for the prevention, alleviation or cure of disease or for the relief of suffering, and not primarily for the purpose of catering to the cravings of an addict, conviction of a violation of any federal or state law relating to narcotic drugs, conviction of a misdemeanor involving moral turpitude or of a felony, and fraud or deception in obtaining a license to practice. The new New York law makes it a ground for the revocation or suspension of a license for the licensee to have "advertised for patronage by means of handbills, posters, circulars, letters, stereoptical slides, motion pictures, radio or magazines."

A bill was killed in New York<sup>19</sup> to make it a ground for the revocation of a license for a licensee to furnish or contract to furnish medical diagnosis or treatment of any kind or nature by or through any other person, whether such other person is licensed or not licensed except when the medical services are to be rendered without charge to the recipient.

**Power of Board to Reinstate Revoked License.**—A new Massachusetts law<sup>20</sup> authorizes the board of registration in medicine at any time after the expiration of one year following the revocation of a certificate issued by it to reissue the certificate and to reregister the affected physician.

**Procedure.**—The Massachusetts law just referred to<sup>20</sup> also specifically requires the board before revoking any certificate issued by it to afford due notice and hearing. The previous law provided for a *hearing* only, so far as specific language is concerned. The new

Mississippi law previously referred to<sup>17</sup> specifies a procedure which the board of medical examiners must follow in revoking or suspending a license and gives the board power in such proceedings to subpoena persons and papers, to administer oaths and to compel testimony. The law also provides that every order of the board is to take effect immediately on its promulgation unless the board fixes a different date and is to continue in effect notwithstanding an appeal to the court.

**ANNUAL REGISTRATION.**—The Massachusetts legislature rejected a proposal<sup>21</sup> to require all licensed practitioners of medicine to register annually with the board of registration in medicine and pay an annual license fee of \$1.

**PERSONS OR ACTS EXCLUDED FROM THE PROVISIONS OF THE MEDICAL PRACTICE ACT.**—An unsuccessful attempt was made in Massachusetts<sup>22</sup> to exempt from the provisions of the medical practice act "dentists, optometrists or chiropodists (podiatrists) when duly registered by their respective boards of registration and practicing as authorized by their certificates of registration."

**MISCELLANEOUS.**—Extensive amendments to the New Jersey Medical Practice Act were proposed in a bill considered in 1938.<sup>23</sup> Among other things the bill, if enacted, which it was not, would have (1) vested in the board of medical examiners the power to examine and license applicants for licenses to practice medicine and surgery, osteopathy, chiropractic, chiropody or optometry, and eventually would have permitted all the practitioners indicated, except optometrists, to practice medicine generally, (2) specifically prohibited the corporate practice of medicine and (3) permitted the use of the injunctive process to restrain the unlicensed practice of medicine.

A series of bills considered and killed in New York<sup>24</sup> under took to treat the practice of radiology as something distinct and apart from the practice of medicine. The bills defined radiology and proposed to prohibit such practice except by a person licensed under the provisions of the medical dental or chiropody practice acts "subject to the conditions and limitations of his license." The bills moreover proposed to authorize municipal corporations to grant permits to physicians, dentists, chiropodists and osteopaths to conduct places for the practice of radiology.

An unsuccessful attempt was made in Massachusetts<sup>25</sup> to provide (1) that the phrase "rendering medical service" as used in the medical practice act should include any treatment of one person by another, by the use or disuse of any means for the purpose of diagnosing, preventing, relieving or curing any deviation from normal condition of mind or body, or for the purpose of preventing, diagnosing or interfering with pregnancy, and (2) that a person should be regarded as holding himself out as a practitioner of medicine if he announced a readiness to practice medicine either directly or indirectly or if he opened an office for the practice of medicine or if he appended titles, words or letters to his name tending to suggest or designate him as a practitioner of medicine in any of its branches.

### C Legislation Affecting Cult Practitioners

**OSTEOPATHS.**—A law was adopted in South Carolina<sup>26</sup> setting up a separate osteopathic practice act and creating a state board of osteopathic examiners to examine and license persons to practice osteopathy. "Osteopathy," the law reads, "shall be defined as a complete system of therapeutics embracing all scientific subjects pertaining to the healing art except Materia Medica. Instead it places emphasis on structural integrity as a major essential to health and that [sic] any derangement of structural integrity is a fundamental cause of disease, by interfering with the natural

26 S. C. Acts 1938 Act No 991

function of immunity and nutrition Practice consists principally in the correction of all structural derangement by manipulative measures including physio and electro therapy, minor surgery, diet, hygiene and obstetrics"

A resolution was adopted in Massachusetts<sup>27</sup> which directs a special unpaid commission, for the purpose of informing the legislature, to investigate the advisability of establishing a board of examination and registration in osteopathy and of having on the statute books an osteopathic practice act The commission is also to consider the advisability of establishing a single board for the examination of applicants for registration to practice any of the healing arts

This resolution was a redraft of a number of proposals pending before the Massachusetts house and senate, some of which<sup>28</sup> proposed to enact a separate osteopathic practice act and to create an independent board of examination and registration in osteopathy to examine and license persons applying for licenses to practice osteopathy

The governor of New Jersey vetoed two bills which, if they had become law, would have conferred stated rights on osteopaths One of these bills<sup>29</sup> would have permitted osteopaths to be employed by boards of education as medical inspectors The other bill<sup>30</sup> would have required that at least one member of the state board of health be an osteopath

**CHIROPRACTORS**—The Massachusetts resolution previously referred to<sup>27</sup> also directed the special commission it created to investigate the advisability of establishing a board of registration of chiropractors and of enacting a separate chiropractic practice act

A similar resolution was killed in New York<sup>31</sup>

Unsuccessful attempts were made in three states<sup>32</sup> to enact separate chiropractic practice acts and to create independent boards of chiropractic examiners to examine and license persons to practice chiropractic

Unsuccessful attempts were made in Kentucky<sup>33</sup> and Rhode Island<sup>34</sup> to amend existing chiropractic practice acts The Kentucky bills proposed to require all licensed chiropractors to renew their licenses annually and to make it a condition precedent to obtaining such annual renewal that a licensee present satisfactory evidence that he had in the preceding year attended the two day educational programs as approved by the Board [of chiropractic examiners] and conducted by the Kentucky Association of Chiropractors The Rhode Island bill proposed that a certificate to practice chiropractic should confer on the holder the right to practice chiropractic in all its branches as taught and practiced in recognized colleges of chiropractic It also proposed that a licensed chiropractor would be a registered physician subject to the same duties and liabilities and entitled to the same rights and privileges which may be imposed by law or regulation upon physicians of any other school of medicine except the practice of major surgery, obstetrics and the writing of prescriptions for drugs for internal medication"

**MISCELLANEOUS CULTS**—Unsuccessful attempts were made to enact separate practice acts and to create independent examining and licensing boards for the cults indicated in the following states magnetic healing, Massachusetts,<sup>35</sup> naturopathy New Jersey<sup>36</sup> and Virginia<sup>37</sup> physiotherapy New York<sup>38</sup> and electrolysis, New York<sup>39</sup>

## II RIGHTS AND DUTIES OF PRACTITIONERS

### A Rights and Privileges

**INSURING PAYMENT OF MEDICAL BILLS**—The Virginia lien law was so amended this year<sup>40</sup> as to provide that where a personal injury results in death the lien of a physician, hospital or nurse caring for the decedent can be asserted against either (1) a judgment or compromise because of the injuries and death or (2) the general estate of the decedent, but not against both

Proposals to grant physicians treating persons injured through the negligence of others liens on any claims, rights of action, judgments, compromises or settlements accruing to the injured persons by reason of their injuries were killed in New York<sup>41</sup>
